RAMMING THE MOLD.
There are many simple little operations which every work ing man performs in the everyday routine of his trade, and
which, though inconsiderable of themselves, nevertheless are not devoid of interest whenmade the subjects of the drafts man's ready pencil. Of such a nature is the process depicted in our sketch-merely a molder busily engaged in ramming the sand into his flask. The pleasing combination of form attracted the casual notice of our artist a few days since, while visiting a large industrial establishment; and in a spare moment he jotted down the lines which, by one of those marvelous processes of photo-engraving, we have caused to be represented in perfect facsimile in thousands of copies of the Scientific American. The design will be an agreeable memento of passibly the daily practice of many into whose hands our paper may find its way, while, perhaps, it may be not entirely without a mission of its own. The earnest face of the workman and the firm grasp with which he wields his rammer show very clearly that he is delivering no gentle blows, and that his task is being done with a will which is a sure guarantee of its thoroughness. Now ramming molds is not a complicated performance, nor does it require the ability of a very skilled artisan; on the con-
trary, it is a very small portion of the multitudinous operatrary, it is a very small portion of the multitudinous operations which must be accomplished before the perhaps great structure, to which the piece of metal in the flask belongs, is completed. But insignificant as this process may be, zeal and thoroughness are just as much called for as in the most delicate manipulations, and no mechanic will ever be the loser by using his best efforts on just such little things. Faithfulness in the accomplishment of small tasks brings with it the ability to perform thoroughly much greater oues; and the working man who proves himself energetic and honest in doing the former will soon find that his talents are needed in larger operations, which will insure him increased credit and profit.

## The American Centennial Exhibition at Philadelphia in 1876.

The committee have adopted the general plan of Vaux \& Radford of New York for the building, known as the "pavilion plan," which contemplates a building which will be mainplan," which contemplates a building which will be maining a rectangular elevation which can be enlarged in any direction to an almost indefinite extent, as the exigencies of the Exhibition may demand.
The principal part of the building covered by the pavilion becomes one spacious hall 408 feet wide and 2,040 feet long, with a transept 408 feet wide and 952 feet long. The vistas, of course, extend 952 and 2,040 feet in length. The building is capable of both central and intermediate points of emphasis, direct lines of transitthroughoutits entire length and breadth, diagonal lines of communication, if deemed necessary, and especially an entire relief from any appearance of contraction because the visitor will always be in an apartment or pavi-
lion 140 feet wide, that opensimmediately into other apartlion 140 feet wide, that op
Features suggested by the plan of Sims \& Brother, of Philadelphia, are to be introduced in coastructing distinct parts of the building. The material will be iron and brick.

The Accidental Color of Bodies of Water.
From early ages, the red color of certain natural deposits of water has been a subject of human speculation, and has given rise to the many grotesque fancies of bloody showers, rivers turned to gore, and the similar ghastly imaginations with which ancient legends abound. Homer in his Miad speaks of a dew of blood which preceded the combat between he Greeks and Trojans; and in the Bible (Exodus, chapter
VII), it is stated that "blood was seen in all the land of Egypt." Similar natural phenomena appearing in more recent times have engendered superstitious fears among the grics as " have been eagerly seized upon by religio of direct and miraculous celestial intervention.
Modern science, however, teaches that fresh water, thus accidentally tinged, owes its colỏr either to the presence of accidentally tinged, owes its color either to the presence of
infusorial animalculæ (euglena viridis, e. sanguinea, astasia hematodes), or to microscopic vegetation (oscillatoria rubes cens, sphceroplea annulina), and sometimes even to small insects, entomostraca (daphnia pulex, cyclops quadricornis), Sea water, as is well known, also presents hues of varied character. Thus the blue or green tint of the ocean on the coast of Greenland has been found due to an animalcule resembling the medusce. Of these minute beings 64 have been found in a cubic inch, 110,392 in a cubic foot, and 23 quadrillions 888 trillions are estimated to exist in a cubic mile Arago considers that the green bands of water noticeable in the polar regions are due to myriads of medusce, the yellow color of which, in connection with the blue tint of the sea produces the green appearance. Near Cape Palmas, on the coast of Guinea, the ocean sometimes becomes covered with animalculæ, floating upon the surface, so that it is said that vessels seem to be sailing through milk. Also on the coast of Portugal, the Atlantic for a space of some five miles square has appeared of a dark red; the phenomenon being due to a minute vegetable known as the protococcus atlanticus. So infinitesimal are these algce that it is estimated that 40,000 of them would not cover a space of over 0.03 of a square inch. The waters of the Red Sea owe their periodic rubefac tion to the presence of a confervoid sea weed, called tricho desmium erythrceum. Pallas states that there exists in Russia a salt lake called Malinovoè Ozen, or raspberry lake, because its salt, as well as the liquor left after distilling the same, is red, and has an odor resembling violets.
Doctor N. Joly communicates to La Nature, from which journal we extract the

Fig. 1. ings, the following interesting details regard ing his investigations into the phenomenon of accidental coloration or rather rubefaction of water in the salt marshes of Villeneuve, a few miles from Montpelier in France. The liquid is of a strongly marked red color, resembling blood, and a quantity taken from the surface and examined with the microscope showed myriads of little beings. Their bodies were oval and long, sometimes cylindrical. While young they are colorless, afterwards turning green, and finally red. The mouth is in the form of a conical prolongation, and is retractile. No eyes could be recognized, nor could the stomach be distinctly made out. By the aid of powerful lenses two flagelliform prolongations, extending from the rear of the animalcule were found, by agitating which it propelled itself in the drop of water on the slide of the instrument. The author was led by this discovery to the conclusion that the protococcus is an animal and a true monad. On further examining the animalculæ after death, they appear globular in form, and hence the mistake made in determining their na ture by previous investigators. A single drop of alcohol, or even of fresh water, in the liquid (on the slide) in which the monads exist, causes them to become motionless and globu lar, while the same result takes place if they be cut off from
 access to the atmosphere, as it ap pears that respiration is absolutely necessary to their existence. Fig. 1 hows the monads (monas Dunalii) live, and magnified 420 times. $a$ ar the young ones, colorless, $b$ are olde and of a green color, while those at $c$
and $d$ are adults, more or less red. Fig. 2 represents the animalculæ after death, in their globular state. It may be noted as an interesting fact that
the protococcus nivalis, or microscopic vegetation to which the phenomenon of red or green snow in the arctic regions is due. They seek the light with avidity, always gathering, when confined in vessels, to the brightest side.
It has been believed by many savants that the artemia salina, a minute crustacean, also aided in giving the water of the salt marshes of the Mediterranean its ruby color. This Dr. Joly does not believe, and he proceeds to demonstrate some curious properties of this strange animal. He states that the artemia owes its own color to its consumption of the monads which are taken into its digestive canal. The artemia is naturally colorless, and its food, together with crystals of marine salt, shows through its body, thus causing it to appear red. Fig. 3 is a section of its digestive tube, in which $a a$ are the monads, not yet digested, and $b$, the cubical crystals of sea salt. The animal itself is represented in Fig. 4, in both its natural size and highly magnified. and $y y$ are eyes; $a$ and eantennæ
$p$ is the incubating pocket, showing the eggs within; 1 to 11 are feet, serving both for purposes of respiration and propulsion ; $a b$ is the abdomen, and $a p$, the caudiform appendage;

$c$ is the digestive tube, colored red by the contained monads. tis a curious fact that the young are produced by parthenogenesis, and are always females.

How a Lawyer Spends his Spare Time
We clip, from the New Orleans Republican, the follo wing nteresting sketch of the profitable manner in which a well known advocate employs his leisure moments. United States District Attorney Beckwith is evidently no less able as a mechanic than as a lawyer. Our contemporary says hat: "When he can get away from his office in the custom house-a way from his books and his briefs-away from his clients and his cases, and the adjustment of 'the doubtfu] balance of rights and wrongs,' then it is that he lets himself, with his lateh key, into a building unoccupied save by himself, goes up into the third story, takes off his coat, rolls up his sleeves and goes to work.
"It is a queer looking rookery, this workshop of Beckwith's. Tools lie scattered around; two or three turning lathes are mounted in one end of the room; beyond them stands an upright boiler and a three horse power steam engine, mounted on an eleven inch base and capable of makng 600 revolutions a minute; a neatly mounted forge, smoke stack, escape pipes, pulleys, bands, benches-everything made and erected by the lawyer-mechanic, the presiding genius of the place.
"The councilor, at whose correctness as a logician and pleader all marvel, astonishes still more those who glance nto his workshop, at the perfectness of the machinery he turns out in his leisure moments. The burly lawyer is master here-files and screws and drills and ratchets are as handy to his touch as authorities in the huge bound books, on his shelves in his room in the granite building. The alchemist in his laboratory, seeking for the mystery which should transmute base metal to gold, was not happier or more enthusiastic than Beckwith is in devising some new appliance in his dusty workshop. Even his bellows he blows by a machine he has invented. The larger turning lathe, which he spent years in making, and months of that time in the perfection of a single screw, is adjustable with the pre cision of a microscope. The governor of his engine did not quite please him, so he has made a new one on a new prinquite please him, so he has ma
ciple, which works to a charm.
'" Understand, all this is the lawyer's pastime. He is no an 'inventor.' He gets nervous when asked if the Beck with sewing machine is his invention, and vehemently denies the impeachment. He takes no sort of pride, either, in his skill as a workman, and we know will not thank us for this intrusion into his workshop."

## Earthquake in Panama.

Panama was visited by an earthquake on the evening of the 13th of October. There were two pretty severe shocks, with an interval of but a second or two between them. The second shock was most severe, and accompanied by a rumbling sound, resembling thunder. In Aspinwall, the shock was felt about ten minutes lacer, and seems to have been more severely felt than in Panama. The people were much frightened, and the fear of a tidal wave added to the excitement. The duration of the shock in Panama was about four or five seconds, so that,it was over before the people had time to run out of their houses. Most people agree that the oscillations proceeded in a direction from southeast to northwest.

In a communication, recently received from Messrs. W. Ladd \& Co., London, they complain that the strictures of Professor Morton, in respect to the bad packing of their cells, are unjust, and say that, while there have been many breakages in the past, due to carelessness of the packers, they have so fully remedied the trouble that they now rarely find the breakage of a single cell out of the large numbers they send to this country.
