Believing Dr. Dawson to be an honest man, the only inference we can draw from a sentence like the last is that he utterly misapprehends the views of modern evolutionists. Certainly nothing in the writings of Wallace, or Darwin, or Lubbock, or Gray can be found to sustain such an ultra Lamarckian method of development. To be guilty of such a mis-statement of the position of another is to forfeit one's claim to any respect as a scientific critic. Even Agassiz' mantle will fail to cover errors so gross and obtrusive.

THE NEW DEPARTMENT OF AESTHETICS.

Professors of the humanities have ever been inclined to look down upon the pursuits of naturalists as little becoming the refinement and dignity of gentlemen and scholars. They have delighted to picture such as turn their attention to the inferior world as eccentric fellows, chiefly employed, like the unfortunate spouse of Lady Jane in the "Ingoldsby Legends," in bug-chasing and poking into all sorts of dirty places for the ugly things that squirm in filth and darkness, solving the infinite (unlike the Breitmann) as one eternalevolution!

We fancy that the cultivators of polite literature will therefore be taken somewhat aghast by the address of the retiring President of the American Science Association, espe cially by that part in which he serenely asserts that the chief requirement of the modern naturalist is an inborn and nighly developed æsthetic faculty.

In the physical sciences everything depends on accurate observation, with strict logical consequences derived therefrom. In biology, on the contrary, while the basis of knowledge equally depends on accurate and trained observation, the logic is not formal but perceptive. Consequently the first requisite for excellence in this crown of the sciences is æsthetic perception.

Savages are usually keen observers, but they would not make good biologists: they lack artistic tact. The native Australians furnish an illustration. In them the absence of this faculty is complete. Oldfield relates that when one of them was shown his own portrait he called it a ship, another said it was a kangaroo, not one in a dozen identifying a portrait as having any connection with himself. Professor Le Conte gives a higher illustration of the same incapacity in a well known class of travelers. Having penetrated to the inmost chamber of the temple of Art. even the Hall of the Tribune at Florence, they stand in the presence of the most perfect works of art, and gaze upon them with the same indifference that they would show to the conceptions of the mediocre artists exhibited in our shops. Perhaps they even wonder what one can find to admire in the unrivaled collection there assembled. They may be highly educated, and good and useful members of the social organism; but they lack the æsthetic sense which enables one to enter into spiritual harmony with the great artists whose creations are before them.

Such unæsthetic and unappreciative persons would not delight a Ruskin, as students of Art; nor would a professor of rhetoric be hopeful of making poets of them. Professor Le Conte maintains that they would make no better students of biology. The æsthetic character of natural history makes it for ever beyond them, just as it prevents the results of its cultivation from being worked out with logical precision.

This view of the fundamental difference between biologi cal and physical science claims accord with the views of such masters of biology as Helmholtz and Huxley. To the genius of the artistic interpreter more than the patience of the collector its future progress will be due. A rising giant has invaded the domain of polite literature, and the humanities must make room!

LIGHTNING RODS.

We published, in our last number, a very interesting communication from Mr. George B. Prescott, the electrician of the Western Union Telegraph Company, concerning an alleged electrical phenomenon, observed during a thunderstorm, within a private dwelling, and described by a correspondent in our paper of August 14, 1875.

The phenomenon in question consisted of electrical dis charges from the water and gas pipes of the dwelling, which was furnished with a lightning rod. The question was as to the cause of the electrical manifestation. Mr. Prescott believed that it was due to the defective connection of the lightning rod with the earth; but in order to satisfy himself fully in the matter, he took the trouble to send an assistant to the locality, and subject the premises, pipes, and rod to

damp earth; or a trench, filled with iron ore or charcoal, may be made available.

The aggregate annual losses of life and property in this arranged conductors were generally employed. But it is evident that a more intelligent class of lightning rod men are needed in their erection; and it is probable that electrical instruction must also be given in our common schools before much improvement can be expected.

If a man, employed to put up a tin pipe to conduct the rain water from the roof to the cistern, were to solder up the bottom of the pipe, thus preventing any flow, his work would be rejected, and he would be stigmatized as a fool. But this is substantially what our lightning rod men are doing every day. They put up rods for the alleged purpose of conducting the electric fluid, but seal or insulate the bottoms of the rods so that the fluid cannot flow into the ground; and the majority of employers are so ignorant of the subject that they are unable to detect the fraud.

The known laws that govern the flow of electricity are almost as simple as those relating to water. If a proper connection exists between the rod and the earth, the building will be protected, for electricity will flow through the rod with the same certainty that water will pass through an open leader from roof to ground. But if the bottom of the pipe be sealed, the water cannot run; and if the bottom of a lightning rod be sealed or insulated, the electricity cannot flow.

by Mr. Prescott, will always show whether they are safe or not. But it may be taken for granted, without a test, that a rod is unsafe which merely has its bottom stuck down a few is to have the bottom of the rod placed in connection with a travel after leaving a disk. large mass of conducting material in the ground.

ANOTHER VIEW OF MR. CROOKES' LAST DISCOVERY. In a recent issue we gave a summary of Mr. Crookes' recent observations on the behavior of delicately suspended pith balls when acted on by a beam of light. In a vacuum the pith balls. and disks of cork similarly suspended, seemed to be repulsed by the light under conditions which demonstrated, Mr. Crookes asserts, a hitherto unrecognized power of light.

Similar observations with substantially the same apparatus were made fifty years ago, so that the discovery is not new if true; it simply reasserts what was generally believed when the Newtonian theory of light prevailed, namely, that luminous radiations are capable of exerting a direct push upon matter. It is strikingly inconsistent, however, with the now dominant theory of light; and according to some careful observers, it is equally inconsistent with fact. Professor Osborne Reynolds suggests that the action of the pith balls or disks is due to the evaporation of some fluid on the surface of the disks, the recoil of the evaporating particles, as they leave the disk, driving it back.

A better explanation, because better sustained by experimental evidence, is that given by Professor Dewar, of Edinburgh, who claims that the heating of the disks is the efficient cause of the action observed. In his investigation Professor Dewar used substantially the same apparatus that Mr. Crookes employed, simply changing the composition of the disks and interposing certain substances having well known effects upon the radiations.

Placing a candle before the apparatus so as to cause a large deflection, he first interposed a vessel of ordinary glass, and the deflection was diminished. On filling the vessel with water, the disks ceased to be deflected. Now it is well known that water, though transparent to light, is almost opaque to heat.

The experiment was then reversed. A smoked piece of rock salt was interposed, shutting off the light but allowing the heat to pass through. The disk remained deflected: so likewise when a solution of iodine in carbon bisulphide was used, a substance opaque to light but transparent to heat. These experiments show that it is not the luminous radiations which have power to move the pith balls, but the obscure radiations commonly known as heat rays.

The next question was: How do the heat rays produce the motion? To test this, disks of rock salt (transparent to heat) and glass (transparent to light) were substituted for those of pith or cork. When a beam of light was thrown upon the clear salt no motion ensued, the radiations passing through unabsorbed. When the light was received on the glass, part was arrested, the glass was heated, and the disk was deflected. The effect was reversed when the back of the rock salt disk was coated with lampblack. The radiations were absorbed by the lampblack at the surface of contact; the lampblack was heated and, by conduction, heated the salt, and the result was (at first) repulsion. Were the lampblack a good conductor, it would heat through first, and then there would be repulsion from that side, or apparent attraction. This in a vacuum: at ordinary pressure the motion is always forward from the side of the disk most heated.

nal may consist of an iron water pipe, as in the present case, of heat from the side of the disk toward it; the distant side or a very considerable extension of the rod itself into wet or became the heated one, and apparent attraction was the result.

Professor Dewar's explanation of these phenomena is simple, and does not involve any new or inexplicable power in racountry, by the striking of buildings by lightning, is im diations. The apparent attraction of the disks by light unmense, but might be almost wholly prevented if properly derordinary pressure is caused, he says, by convection currents. The air or gas in front of the disk is heated, and, rising, tends to cause a vacuum; the disk consequently advances, pushed forward by the power that drove the ship of the "Ancient Mariner":

"The air is cut away before And closes from behind !"

In a vacuum the effect is different: the disk is repulsed instead of attracted—repulsed by the recoil of the residual molecules of the gas, which leave the beated side of the disk at an increased velocity after impinging upon it in the course of their travels.

"What takes place is this: The particles of the gas are flying about in all directions, with a velocity which depends on the temperature. When they impinge on the hexted disk, they go off with a greater velocity than those which go off from the colder side, and hence there is a recoil of the disk. When the gas is at all dense the particles get a very short way before they are met by another and sent back, and so the velocity gets to be a common velocity before any visible action takes place. When the gas is rare, the particles may get a long way off before they meet others, and so the action becomes perceptible."

The vacua employed by Professor Dewar were formed by the charcoal method, the density of residual gas being re-Tests of lightning rods with the galvanometer, as directed duced to one four-millionth of its density at ordinary pressure. In such a vacuum, the average path between two collisions is about 1 foot against an average of one four millionth of a foot at ordinary pressure. It will be seen, therefore, feet into dry earth. We repeat, the golden rule for safety | that the particles may have relatively a very long way to

> For the benefit of those who have dreamed of securing a profitable direct motive power derived from solar radiations, it may be added that the total work done by the radiations in these experiments did not amount to the five-millionth part of the available energy received by the movable surfaces.

EXPLOSIONS IN GUNPOWDER MILLS BY ELECTRICITY.

A correspondent remarked, some time since, that the mysterious explosions of some powder mills may probably be due to an electric spark given off by persons dressed in woolen clothing, who, when the air is dry, may (by friction of their clothing or feet) produce from their finger ends a spark of electricity sufficient to ignite a gas jet. He submitted the question whether it would not be possible that men at work in powder mills may create so much electricity in their bodies that, when their hands come in contact with metallic conductors, it may be, if not sufficient to ignite powder, enough to ignite some inflammable gas generated from the chemica's.

This letter has drawn the attention of the London Chemical Review, which states that in England they have often seen in American journals the statement that an electric spark, sufficient to ignite gas, may be given off by the human hand; but the editor says that he never heard of such cases on his side of the water. We know that the air in England and all the countries of Western Europe is very damp, owing to the prevailing west winds and the absence of extensive areas of dry land, blowing over which the wind would become very dry, as are our west winds, coming over our prairies.

It is asked what inflammable gas may be generated in the manufacture of gunpowder? To this, it may be answered that, in the manufacture of fulminates for percussion caps, inflammable vapors, as nitrous ether, etc., are given off, while the dust of gunpowder and even of charcoal, when floating in the air in a proper quantity, may form an explosive mixture. Even the dust from the mineral grahamite, which in its character is very sin ilar to gunpowder charcoal, has repeatedly exploded in the mines in Western Virginia, when mixed with air in the right quantity. It is well known among electricians that a weak electric spark will more easily explode gunpowder than a strong, intense spark; the latter will scatter a heap of gunpowder without igniting it, but, when the spark is weakened by substituting for a part of the conducting metal a less conducting material, such as water or a moistened thread, then ignition will readily take place.

actual electrical tests with the galvanometer.

The result was that the lightning rod was found to be so sadly defective in its ground connection that it could not conduct the electricity into the earth, except feebly; and whenever a thunderstorm occurred, the house became charged with electricity, and the current, being unable to pass down the rod, made its way through the building to the water pipe, and escaped through it into the ground. The details given by Mr. Prescott are quite interesting. He advised the immediate connection of the rod with the water pipe, which would thus to serve as an extensive conducting terminal for the rod, ensure the safety of the building, and put an end to the electrical manifestations among the pipes before mentioned.

This case is a representative one, as the rod was put up in the same defective manner as are the majority of rods, that is, the bottom of the rod was simply stuck down a few feet into the ground or rock, and thus practically insulated.

We have repeatedly advised our readers that a lightning rod, in order to serve as a protection for a building, must

Other experiments were made with disks of sulphur, clear and ordinary; and with transparent disks coated on one side with white phosphorus, which is opaque to the ultra-violet

rays. In the latter case, when the disks were acted on by light, chemical action ensued with disengagement of heat, resulting in a motion of the disks away from the side heated. The reverse was demonstrated by bringing ether near a disk; have a large conducting terminal in the earth. This termi- a piece of ice. The chilling substances caused a radiation the tube has thirty-six grooves.

We acknowledge that we have no positive evidence that powder mills have actually been exploded by electricity; but the possibility of such a cause was only suggested in our paper, and it must be admitted that this suggestion is not unworthy of serious attention.

Resignation of Commissioner of Patents.

The daily papers announce the resignation of Mr. J. M. Thacher, the present Commissioner of Patents, to take effect October 1. His successor has not yet been announced by the President, but the name of R. H. Duell, of Courtlandt county, N.Y., is mentioned as the probable appointee. Mr. Duell is reputed to be a lawyer of considerable ability as well as a first class politician. He was formerly a member of Congress.

NEW RUSSIAN GUN.-A great cannon, lately built at the works at Oboukowsky, has cost \$65,000, and weighs 40 turs. It is a breech loader, entirely in crucible steel, 20 feet 6 and doubtless the same effect would have been produced by inches long; its largest ring is 571 inches in diameter, and
