Removing River Obstructions.

To the Editor of the Scientific American:

In your issue of the 16th inst. I noticed an article on the removing of sand bars, etc. The idea of floating or washing out obstructions of this kind in rivers is not new to me, as I have advocated the system for the Mississippi, with its wonderful shiftings, on the following plan. Have large flat bottom boats with heavy steam machinery, and supplied with fans or force pumps whose power would be conveyed to the object to be removed through hose weighted so as to drag on the bottom when the power is being exerted against the obstruction. The hose (one or more) to be put out from quired. In the after part of the boat, and at proper depth as Illustrated by the British Flora," the author says: "The the forward part of the boat and adjustable to the depth rebelow the surface of the water, have revolving attachments, constructed so that they will draw the water from under the center of the boat and throw a swell toward each side, which will carry a quantity of the floating or dislodged mat ter beyond the channel. To prevent creating an obstruction by the settlings down stream, it would only be necessary to run further down each time the route is gone over. To keep a river open in this way it would require boats to be stationed at such distances as could be gone over each day, or as occasion required, and I believe the cost would be much less than dredging, and certainly always leave a clear R. H. ANDREWS. channel.

Washington, D. C., Sept., 1882.

NATURAL HISTORY NOTES.

Insectivorous Plants .- A. F. W. Schimper, in the Botanische Zeitung, gives a detailed description of several insectivorous plants native of North America. He describes in this paper more fully than has been done before the ascidiform leaves of the side-saddle plant (Sarracenia purpureu), and has determined that the products of decomposition of the insects and other organic substances found in the "pitchers" enter the cells of the leaf, as is shown by the changes which take place in the protoplasm of the cells thus affected. In these cells the author noticed a phenomenon closely resembling that described by Darwin as occurring in Drosera, under the name of "aggregation of protoplasm." In Sarracenia, however, the aggregations consist of a concentrated solution of tannin-a substance always present in the cell sap. Of North American Utricularia (bladder warts), U. cornuta was especially examined and found to present several very singular points of structure. The plant possesses no true root, the rhizome branching into several root-like organs, which bear the bladders in great quantities, and which the author believes to be homologous with the floating leaves of the aquatic species. The bladders are similar in form to those of U. vulgaris (but want the "antennæ"), as is also their histological structure, which he describes in detail. They contain, in addition to inorganic bodies, small animals and algæ, especially diatoms, rotifiers, and crustacea. The animals were never found alive, but usually much swollen and decomposed; and this was also the case with the diatoms, the contents of the bladders being apparently poisonous to a warning in respect to the quality of milk to be used, the both animals and plants. The hairs of the bladders appear necessity of good pasturage and pure water for the cows, as to act as organs of absorption; and in the contents of their cells changes were observed similar to those described in the treats as follows on the digestibility of milk and its benefit cases of Sarracenia and Drosera. As in Dionaea, an excess of nutriment is injurious to the plant.

The Elephant in Ceylon.-At a meeting of the Leeds Naturalists' Club, the president (Mr. B. Holgate, F.G.S.) related some curious particulars which had been furnished to him that we are able to indorse the writer's recommendation of a tions was one that ages since the mountains rose precipiby the Rev. R. Collins, of St. Silas's Church, Hunslet, who milk diet for the ailment he specifies. has spent twenty-five years in India and Ceylon. Mr. Collins states that elephants are not now allowed to be shot, as they once were, but are permitted to wander at will in the forests belonging to the government. They live to the age of about one hundred and thirty years, and "come of age" at forty. There are three sizes of them in the same herds, and when they are young the size that they will attain is pretty nearly known by the number of their toes. Those which grow to the largest size have eighteen toes, five on count the more difficult of assimilation. It cannot, there- lation with the discoveries and deductions of science, each of the two fore feet, and four on each of the hind ones. Those which grow to a medium size have seventeen toes, five on each of the fore feet, as before, and four on one hind strength after long, severe illnesses. A residence at the deaden its flow for eight miles above and to submerge the foot, and three on the other. The least size of elephant has

It in the arid landscape, with its finely divided foliage and showy pink or white flowers, it at once attracted the attention of the whole party. It has been named Rosa minutifolia by Dr. Engelmann, who describes it as "a most striking and lovely species, distinguished from all other roses by its minute deeply-incised leaflets." The species is quite pecu- prived of a large proportion of cream, it is not calculated to liar among its American congeners, and even among the roses of the Old World, so that it is difficult to determine its true position. As seeds have recently been collected, we may hope to soon see the plant in cultivation.

The Colors of Flowers .- In a lengthy and interesting article by Grant Allen, in Nature, on "The Colors of Flowers, beforehand in the tissues of the plant, ready to be brought out at a moment's notice. And all flowers, as we know, easily sport a little in color. But the question is, Do their changes tend to follow any regular and definite order? Is there any reason to believe that the modification runs from any one color toward any other? Apparently there is. All flowers, it would seem, were in their earliest form yellow; then some of them became white; after that a few of them grew to be red or purple; and, finally, a comparatively small number acquired various shades of lilac, mauve, violet, or blue. Some hints of a progressive law in the direction of a colorchange from yellow to blue are sometimes afforded us even by the successive stages of a single flower. For example, one of our common English forget-me-nots, Myosotis versicolor, is pale yellow when it first opens; but as it grows older it becomes faintly pinkish, and ends by being blue like the others of its race. Now, this sort of color-change is by no means uncommon; and in almost all known cases it is always in the same direction-from yellow or white, through pink, orange, or red, to purple or blue. Thus, one of the wallflowers, Cheiranthus chamæleo, has at first a whitish flower, then a citron-yellow, and finally emerges into red or violet. The petals of Stylidium fruticosum, are pale yellow to begin with, and afterward become light rose-colored. An evening primrose, Enothera tetraptera, has white flowers in its first stage, and red ones at a later period of development. Cobas scandens goes from white to violet: Hibiscus mutabilis from white, through flesh-colored, to red. The common Virginia stock of our gardens (Malcolmia) often opens of a pale yellowish-green; then becomes faintly pink; afterward deepens into bright red, and fades away at last into mauve or blue. Fritz Müller noticed in South America a Lantana which was yellow on its first day, orange on the second, and purple on the third. The whole family of Boraginaceae begins by being pink and ends by being blue. In all these, and many other cases, the general direction of the changes is the same. They are usually set down as due to varying degrees of oxidation of the pigmentary matter. -----

Milk as a Curative Agent.

Under the above heading a writer in Harper's Weekly, after well as the care in keeping the milk in a cool, cleanly place, to dyspeptics for complaints.

Milk has the power to absorb obnoxious gases and effluvia from the air around it, and it should not be forgotten that the purest butter that ever was made may become tainted and poisoned in one short hour by objectionable surroundings. Comes now the question of the digestibility of milk.

goat's milk would naturally convey the impression that that fore, be recommended for the very delicate, but it is a grand seaside to induce a healthy appetite, and a diet consisting forests just above the rapids. Mr. Brazee, who has been

and C. G. Pringle, while they were riding along a road termission, or evil results may follow. Cream, if taken should be taken with breakfast, and the more fresh it is, and the more good and pure the milk from which it has been taken, the better will be the result. The cream of goat's milk is probably better than even that of the cow.

> Skim milk is very nutritious, but, of course, being desustain the animal heat so well.

It is not every invalid who can take buttermilk, but it has, nevertheless, much to recommend it as a cooling nutritive summer drink. I might almost claim for it tonic properties; however, there is no doubt that, taken an hour or two before any of the ordinary meals of the day, when a feeling of emptiness and fatigue is experienced, it is of different hues assumed by petals are all, as it were, laid up | great service. The delicate should have it as fresh as pos-

Milk, talking physiologically, is demulcent, and therefore of great service in many cases of cough and lung irritation, as well as in dyspepsia. I need hardly say a word about the virtue of milk as a medicine for those suffering from consumption. In this case it ought to be drunk warm from the cow; it is certain then to be unadulterated. Too much of it can hardly be taken, so long as it agrees.

In all kinds of internal irritabilities, even in dysentery itself, milk is invaluable, and the emollient effects of milk warm from the cow are well marked in cases of chronic or winter cough.

A Sliding Mountain in Oregon.

The government engineers engaged upon the ship canal around the rapids where the Columbia River cuts through the Cascade Mountains, and the engineers of the Oregon Railway and Navigation Company, whose railroad runs beside the government canal, have discovered that a point of the mountains, of tremendous height and three miles in extent, is moving down an incline into the river. The fact of a moving mountain is strange, but not incomprehensible. It seems, says an intelligent correspondent of the New York Times, that the great river and the ravines that point to it have cut their way down through a superincumbent mass of basalt into a substratum of sandstone. This sandstone, we will suppose, presents a smooth surface, with an incline toward the river; the river cuts under the basalt into the sandstone, and the natural effect is for the superincumbent basalt, acting like a similar formation of ice in a glacier, to slide down hill.

The same gentleman says, on the authority of Mr. Thielson, engineer in chief of the Western Division of the Northern Pacific Railroad, that when an examination was made a year ago of a disused portage tramway past that point, the track was found to be twisted as much as seven or eight feet out of the true line in some places, caused beyond doubt by a movement of the mountain. It seemed certain to Mr. Thielson that there was a movement of a tremendous mountain spur opposite this piece of road. The correspondent goes on to say :

"It is a fact well known to all river men that above the Cascades, where the river is tranquil, the waters cover a submerged forest, whose trunks still stand with their projecting limbs to attest some wonderful phenomenon. It has been a query in the minds of all as to what convulsion of nature or process of time caused this overflow of waters. The writer's views so accord with the experiences of one Over thirty years ago I saw the dead trunks standing beof the editors of this paper in the use of various kinds of milk neath the waves, and the interest in this connection was inin an obstinate case of dyspepsia on a member of his family, creased by learning from the Indians that among their traditously at the river's side, and a great arch of stone spanned the river from shore to shore, and that their canoes passed underit. Tradition further says that in course of time a great earthquake threw down the arch and blocked the river, causing the cascades as we see them now. It is not often that Indian tradition is so specific in detail. As the records A glance at a table of the composition of cow's, ass's, and of the aborigines of this region are very transient, it is possible that this story rests on some fact of natural history of of the goat is the richest. This is so, but it is on that ac- not very remote occurrence. Joining tradition and specuwe must conclude that some convulsion of nature has adjunct to the diet of those who are just beginning to regain thrown great masses of rock into the stream sufficient to
