ASPECTS OF THE PLANETS FOR JULY. VENUS

lover of the stars, she deserts the western sky, where she has near together, and are in conjunction on the 12th at 1 o'clock months, and is seen there no more. She is not lost, however, i tion, encounters Mercury eleven hours before superior confor when she disappears from the sun's eastern side as evening star, she reappears on his western side as morning star. This event is called her inferior conjunction. It takes place on the 11th, at 9 o'clock in the evening. She then passes between us and the sun, with her dark side turned toward the earth, like the moon at new moon. In like manner she made the passage on the never to be forgotten 6th of December, 1882, but with this difference:

At the present inferior conjunction, she passes above the sun, and is invisible. At the previous inferior conjunction, she was near one of her nodes, and was projected on the sun's surface as a round black orb, while the grand phenomenon of her transit made the event memorable to every observer. The like will not be seen again until the year 2004, for, at every intervening inferior conjunction, she will pass above or below the sun, and no mortal eye will detect in the evening. her presence as she passes.

The reason is plain. The orbit of Venus is inclined about three and a half degrees to the ecliptic, so that she is half the time above the sun's path, and half the time below it. She must be at or near one of her nodes or crossing points to bring her directly between the earth and sun, and make her passage or transit visible to terrestrial view.

The interval between an inferior conjunction and the one next succeeding is 584 days. This is called the synodic period of Venus, although she completes her revolution around the sun in 224 days. As the earth and Venus are both moving, nearly three revolutions of Venus are required to bring the sun, Venus, and the earth into line.

Our brilliant celestial neighbor moves very rapidly in this portion of her orbit, and soon becomes visible as the brightest star that shines in the morning sky. She will be worth getting up early to behold at the end of the month, rising then a few minutes after 3 o'clock, nearly two hours before the sun. The waning crescent has become the waxing crescent. Hesperus, the evening star, is transformed into Lucifer, the light bearer. Beautiful as she will be when, a is evening star. He is near Uranus during the whole month, month or two hence, she anticipates the dawn, her morning setting about half an hour earlier on the 1st, and about a charm never quite equals the lovely appearance she puts on amid the glowing splendor of the twilight sky or the grand and pass each other. For they are in conjunction on the proportions she assumes as she slowly sinks below the western hills.

seems to be on the eve of making important discoveries. She is so closely veiled by an atmosphere of clouds, that it is almost impossible to obtain a glimpse of anything upon the green tint of Uranus, in contrast with ruddy tint of Mars, body of the planet. M. Trouvelot has not been deterred by the difficulties in the way, but has made diligent studies of Venus since 1877. During that year, he found two remarka- declination is 6° 54' north; and his diameter is 58'. ble white spots on opposite limbs of the planet near the extremity of the cusps or horns of the crescent. The southern evening; on the 31st he sets at half past 9 o'clock. spot was the brighter of the two, and appeared to be composed of many bright points, forming on the northern border is evening star; besides being in conjunction with Mars, his puff out the buttons into almost perfect spheres, a shape that a row of brilliant, star-like dots of light. The spots disappeared in about three months. Since that time-February, 1878-M. Trouvelot has observed on 242 occasions, either one place on the 30th, at noon-day, the planet being 2' north of tachment to a sewing machine which rotates the rope of yarn or the other of the luminous spots and occasionally both of the star. The approach is so close as almost to become an and feeds it along by intermittent adjustable feed to acthem, and has made 120 drawings. Since April of the present year, he has not lost sight of the northern spot, which alone was visible at that date. The spots are not affected by and Mr. Lockyer, studying the planet through the 15-inch Conn. It is used also for staying the ends of ropes for the the planet's diurnal rotation, and he therefore infers that the equatorial in the Observatory at Nice, found a bright spot running rigging of ships, reefing points, clothes lines, and axis passes either through or very close to their center. The near the equator. It was a very difficult object, and much other cordage, to prevent untwisting, and to produce a solid spots appear almost permanent, and Trouvelot thinks they doubt was felt as to its real existence. But repeated ob- end for passing through blocks, eyebolts, etc. are the summits of high mountains projected beyond the cloudy envelope that hides the planet.

of the most skillful observers in astronomical ranks, as well rotating on its axis as they watched the progress of the bubbles;" and it is assumed that, as this girder gave way, as one who holds a place among the highest for his drawings luminous spot over the disk, though they were nearly the extra weight thus thrown upon the others caused the acany that human skill has yet attained. We trust his prac- annals, and "unknown" will no longer find place in the ticed eye will detect something more than two bright spots tables for the axial rotation of Uranus. on the face of our interesting neighbor. If only he could bring to life and light her long lost satellite, astronomy tion is 2° 53' north; and his diameter is 3 5". would bestow upon him distinguished and immortal fame. Uranus sets on the 1st about a quarter after 11 o'clock in posed on coming in contact with molten iron or steel, its

joined to the sun on his inferior or inner side. In the latter | ing on the 1st an hour and a half before the sun, and on the case, on the superior or outer side.

Although, in reality, Mercury and Venus are as far apart is evening star until the 11th, when, to the regret of every as they can be, viewed from the earth they appear to be declination is 21° 26' north; and his diameter is 16". reigned with queenly majesty and grace for nearly ten in the morning. THE MOON.

The July moon fulls on the 8th, at 11 minutes after 5 19th near Saturn. On the 21st, the day before new moon, in conjunction with Uranus and Mars. The moon thus Mercury is in conjunction with Jupiter on the 23d, at 3 passes each planet in turn, and shows the order of their position in regard to the sun, the old moon drawing near Neptune, Saturn, and Venus, on the sun's western side, and the new moon approaching Jupiter, Mercury, Uranus,

The moon occults in her path only three small stars visible in this belt of the world's territory. Observers from Neptune to observers in some localities between 44• and 74° south latitude, and occults Venus, that most charming is evening star throughout the month, but will soon be too sight, to some favored mortals whose lookout lies between

HOW PILE BUTTONS ARE MADE.

The commonest articles of daily use sometimes awaken curiosity as to the method of their production; one of these is the buttons used on coach cushions and for similar purposes. They appear to be balls of pile or plush, like those ball ornaments used sometimes on ladies' and little girls' dresses. But these ornaments are usually made by hand, by around a central string, the yarn being cut around the center with a sharp knife, the paper or pasteboard torn out, The right ascension of Jupiter on the 1st is 8 h. 40 m.; and the pile or yarn being beaten into fluffy form and shaped with scissors. In the manufacture of coach trimming buttons the principle is the same, but the method is different.

> The woolen yarn of which the buttons are composed is slightly twisted into a rope of the proper diameter, and is then circumferentially sewed at distances of about half an inch. At these sewings the rope is cut into sections, making a slightly convexed disk on the side of the free ends of the is then placed on an eyed base of thin metal, such as forms the under side of cloth buttons, and the base and worsted are forced into a tube by a press, the sides of the tube turning securely the tightly sewed edges of the woolen fluff. As the button comes from the press it is almost flat, instead of being nearly globular, the pile top being slightly convex and the bottom of metal standing out from the mass.

> Now comes the most interesting portion of the manufacture, and its last stage. The flat buttons are placed in a rotating perforated cylinder, and turned over a steaming caldron of hot water. Only a few minutes' exposure suffices to they will retain until after long compression.

The around and around sewing is done by an ingenious atcommodate the different sizes of buttons. This attachment There has been recent news from Uranus. M. Perrotin is the invention of an ingenious mechanic in Bridgeport,
