ESTABLISHED 1845.

MUNN & CO., Editors and Proprietors. PUBLISHED WEEKLY AT

No. 361 BROADWAY, NEW YORK.

O. D. MUNN.

TERMS FOR THE SCIENTIFIC AMERICAN.

A. E. BEACH.

The Scientific American Supplement is a distinct paper from the SciENTIFIC AMERICAN. THE SUPPLEMENT is issued weekly. Every number contains 16 octavo pages, uniform in size with SCIENTIFIC AMERICAN. Terms of subscription for SUPPLEMENT, 50.0 a year, for the U. S., Canada or Mexico. \$6.0 a year to foreign countries belonging to the Postal Union. Single copies 16 cents. Sold by all newsdealers throughout the country. See prospectus, last page. Combined Rates. The SCIENTIFIC AMERICAN and SUPPLEMENT will be sent for one year, to one address in U. S., Carada or Mexico, on receipt of seven dollars. To foreign countries within Postal Union eight dollars and fifty cents a year.

#### Building Edition.

Building Edition. THE ARCHITECTS AND BUILDERS EDITION OF THE SCIENTIFIC AMERI-CAN is a large and splendid illustrated periodical, issued monthly, con-taining floor plans, perspective views, and sheets of constructive details, pertaining to modern architecture. Each number is illustrated with beautiful plates, showing desirable dwellings, public buildings and archi-tectura' work in great variety. To builders and all who contemplate build-ing this work is invaluable. Has the largest circulation of any architec-tural publication in the world. Single copies 25 cents. By mail, to any part of the United States, Canada or Mexico, 82.06 a year. To foreign Postal Union countries, \$3.00 a year. Combined rate for BUILDING EDITION with SCIENTIFIC AMERICAN, and SUF-PLEMENT, \$9.00 a year. To foreign Postal Union countries, \$11.00 a year. Combined rate for BUILDING EDITION, SCIENTIFIC AMERICAN and SUF-PLEMENT, \$9.00 a year. To foreign Postal Union countries, \$11.00 a year.

## Export Edition of the Scientific American,

**Export Edition of the Scientific American**, In which is incorporated "LA AMERICA CIENTIFICA E INDUSTRIAL," or Scanish edition of the SCIENTIFIC AMERICAN, published monthly, uni-form in size and typography with the SCIENTIFIC AMERICAN. Every num-ber contains about 30 Pages, profusely illustrated It is to: elinest scientific, industrial export paper published. It circulates throughout Cnba, the West Indies, Muzico, Central and South America, Spain and Spanish pos-sessions-wherever the Spanish language is spoken THE SCIENTIFIC AMERICAN EXPORT EDITION has a large guaranteed circulation in all commercial places throughout the world. \$300 a year, post paid to any part of the world. Single copies 25 cents. The Manufacturers and others who desire to secure foreign trade, may have large and handsomely displayed announcements published in this edition at a very moderate cost. MUNN & CO., Publishers, 361 Broadway, New York.

501 Broadway, New York. 17 The safest way to remit is by postal order, express money order, draft or bank check. Make all remittances payable to order of MUNN & CO.

LESSONS OF A GREAT DISASTER.

The North German Lloyd steanship Elbe, bound from Bremen for New York, was sunk in a collision with a small steamer fifty miles off Lowestoft, England. between 5 and 6 on the morning of January 30.

But twenty survivors escaped in one of the boats. All the other passengers and crew, numbering about 334 souls, were lost. The weather was clear, but cold. and a strong wind, almost a gale, was blowing.

Chief Engineer Neussell, who was saved, says the stem of the steamer which rammed the Elbe struck her about 150 feet forward of the rudder, or just abaft the engine room. The engines were not damaged by the collision, but the water soon poured in, and although the steam pumps were put to work, in about three minutes it proved to be useless. The fires were soon extinguished and the engines and pumps stopped working.

Mr. Keller, the London manager of the North German Lloyd Steamship Company, says:

"The Elbe was struck right on a bulkhead partition, so that both the watertight compartments which it divided were instantly filled."

There was no longitudinal bulkhead.

The shock and crash of the collision aroused everybody. The steerage was in a panic in a moment, and men, women and children, half dressed, or in their night clothes, came crowding up the companionways to the deck.

As the other steamer backed off and drew her stem out of the great cut made in the side of the Elbe, the latter careened over to port and began to settle by the stern. Three boats on the port side were lowered, but all except one were lost. By this time the list of the ship to port was so great that the starboard boats could not be lowered; and soon after the ship went down by the stern, and the whole crowd of people on board were engulfed in the waves. The single boat with twenty-two persons was picked up by Readers are specially requested to notify the publisher in case of a fishing smack. The colliding vessel was a small any failure, delay, or irregularity in receipt of papers. steamer from Rotterdam named the Crathie. Her stem was badly crushed, but she succeeded in reaching port in safety.

Among the lessons derivable from this disaster, we may note the inadequacy of the present means of saving life. The Elbe was provided with ten life-boats. besides life-rafts and collapsible boats. In consequence of the careening to port, the five starboard life-boats could not be launched. The life-rafts and other boats appear to have been of no account. Is it not possible his disk, eastern standard time : for ingenious minds to study out new forms of life-savin which the Elbe was placed ? Cannot some practical will be half way across about 9:55. system be devised for launching boats from the upper side of a careened vessel?

recognizable as the more northerly of the two, the distance separating them being about three degrees.

It will be interesting to remember when looking at Mercury on this occasion that the planet is, at the time, close to its perihelion point or nearest approach to the sun.

It will receive (shall we say enjoy ?) a degree of heat ten times as intense as that which the sun pours upon the earth, and yet toward the end of last December the solar heat on Mercury was less than half as great as it will be on February 9. This arises from the fact that the orbit of Mercury is very eccentric, so that its distance from the sun, which is only 36,000,000 miles on the average, varies to the extent of nearly 15,000,000 miles. Luckily for us, the sun doesn't sport that way with the earth.

Every lover of the stars will rejoice at the return of Venus to the western sky. During the month she will gradually draw away from the sun and brighten a little, but she is still far in the distant part of her orbit and the real glory of her re-entry as the queen of the evening is a spectacle reserved for the spring. At the end of February, however, she will already have become a conspicuous object, brightening the barren region that lies on the borders of Cetus and Pisces.

Mars remains in Aries during the first half of the month. In the latter half his eastward motion will carry him over into Taurus and he will swing slowly past the Pleiades on their southern side. His splendor has departed, he is moving farther away, and the sun is getting lower on that southern pole of his, whose snows (if snows they are) sparkled so brilliantly and vanished so swiftly at the touch of summer last year.

But while Mars fades, Jupiter continues a feast for the eyes of all those happy people who know the joys of the telescope. His marvelous panorama of cloud belts and changing spots, the delicate blue of his poles, and the gorgeous decoration of white and ruddy vapors that encircles his vast equator, are sights of another world that no thoughtful person should miss seeing. Jupiter is in the eastern part of Taurus some four degrees northeast of the star Zeta, and almost directly north of Orion; but he needs no star to point him out, and no constellation to emphasize his presence. He crosses the meridian about 9 P. M. at the beginning of the month and about 7 P. M. at the end.

I give, as heretofore, two or three dates on which the shadows of some of Jupiter's satellites can be seen on

February 10, at 7:41 P. M., satellite I will pass upon ing devices that shall be available under the conditions ' the disk ; its shadow will follow at 8:45, and the latter

February 22, at 9:19 P. M., satellite III will pass upon the disk; its shadow will follow at 2:08 o'clock The weakest spot in nearly all steamers appears to the next morning, and the latter will be half way be at or near amidships. A blow near this point has across about 3:38 A. M. In the mean time, at 2:21

February 24, at 8:55 P. M., satellite II will pass not an unsinkable ship be invented? We think it upon the disk; its shadow will follow at 11:18, and the can. THE HEAVENS IN FEBRUARY.

An excellent opportunity to see the shy planet Mercury is offered this month. Since the astronomers watched it crossing the sun's face last November, Mercury has passed around the farther side of the sun and is now preparing to swing once more into line between the solar orb and the earth, but this time it will not be seen against the sun. On February 9 the little planet will attain its greatest elongation east of the sun and will be seen shining in the sunset glow low in the west. It should be looked for, as soon after sundown as possible, two or three days before and after

As the moon runs through the circle of the Zodiac she will in turn pay her respects to the various planets encountered on her way. At midnight on the 4th she will meet Neptune; at 10 P. M. on the 5th she will pass Jupiter, and at 10:36 P. M. on the 14th Saturn will bask in her rays. It becomes the turn of Uranus to meet the swift-footed goddess on the evening of the 15th. Renewing her course in the west, in the last week of the month the moon will pass Mercury, returning sunward on the 24th, and will overtake Venus on the 26th.

## Acetylene as an Illuminant,

acting as an illuminating agent on account of the high visionally transcribed. The cost of preparing calcium the top being formed of oak and the shoe of cast steel, percentage of carbon-92 per cent-which it contains, and because of the fact that being an endothermic compound, the heat evolved in its combustion is greater than that corresponding with the number of heat units generated by the oxidation of its constituents. Save in the laboratory, it has not hitherto been prepared in the unmixed state, and its utilization has not been contemplated, as the ordinary methods by which it can be obtained are comparatively costly. Its qualities as an illuminant are, however, sufficiently good to warrant the supposition that various applications may be found for it, should a cheap method of manufacture be devised. A considerable amount of rumor, couched in exaggerated language, has lately been current concerning the production of acetylene on a scale of sufficient magnitude to bring its adoption as an illuminant within the bounds of possibility. The bulk of the reports have been transatlantic in all senses, and too much regard should not be paid to them, but there is nevertheless a certain core of fact in these announcements which may be profitably sifted out.

The subject being eminently topical, Professor V. B. Lewes has taken advantage of it to deal in a popular manner with the various suggestions that have been made for turning acetylene to account, should it prove practicable to prepare it at a cost which would enable it to compete upon equal terms with other combustible illuminants. The dissertation alluded to was read on January 16 before the Society of Arts, and contains, inter alia, a useful recapitulation of the chief properties of acetylene and of its mode of preparation. It has long been known that certain metals, notably those of the alkaline earths, are and using the mixture direct as an illuminating gas of capable of forming carbides, which when treated with high candle power, but not of such richness as to be water evolve acetylene, the hydroxide of the metal used being simultaneously formed. shown that only a restricted group of substances can the proportions might result in the production of an be regarded as fixed at the high temperatures which can explosive mixture. A second, and in some ways prebe obtained by means of the electric furnace, silicides, ferable arrangement, would be to enrich common coal borides, and carbides being prominent among these, gas with acetylene in place of gas from cannel or of and many such substances have been experimentally prepared by him. That calcium carbide can be obtained in a like manner is a necessary corollary; in addition to this it has been empirically found that the preparation of this substance can be effected with considerable ease. A mixture of powdered lime and anthracite exposed to the temperature of the electric furnace yields calcium carbide, the lime being reduced to thereupon is useless at present, further and more indecalcium at the expense of a portion of the carbon, the remainder of the latter uniting with the calcium; the formula  $CaC_2$  has been assigned to the calcium carbide prepared in this manner. The sp. gr. of calcium carbide is stated to be 2.262, this low figure being due to and for numerous purposes, of a self-contained source the fact that calcium is, next to the alkali metals, one of gas of high illuminating power. The bare fact that of the lightest of the metallic elements. When calcium a portable solid substance can be caused to generate a carbide is brought into contact with water, acetylene gas of the required quality by mere contact with a is evolved and lime formed, according to the equation  $CaC_2+HO=C_2H_2+CaO$ ; when excess of water is present, the lime resulting from this decomposition is, of cluding railway carriages, where compressed oil gas course, slaked. It is seriously proposed to manufacture calcium carbide for the purpose of preparing acety- nal lights and buoys in positions to which access is nelene either for immediate and local consumption as an cessarily intermittent, and the domestic supply of illuminant, or for distribution from a central station isolated houses, give considerable scope for a material as the enriching agent in ordinary coal gas, or as the fulfilling the essential conditions of simplicity, cerchief constituent of illuminating gas of special grade. tainty, and safety in use. For purposes of this kind. A yield of 5 cubic feet of acetylene per pound of cal- the question of cost is altogether subsidiary, and the cium carbide is claimed, the gas obtained being very rivals with which a new illuminant would have to nearly pure-98 per cent  $C_2H_2$ . The powerful and dis- compete are themselves handicapped by many disagusting odor of acetylene would give warning of its bilities. Should failure attend the more ambitious escape from leaky fittings-a point of some moment, as scheme to use acetylene as a general lighting and enit is undoubtedly possessed of toxic properties. The riching agent, a fair measure of success may be sesolubility of acetylene in water-about 1.1 volume cured in the less grandiose direction.-The Engineer. for 1 volume of water-is somewhat against ease of handling and distribution, but the gas is a good deal less soluble in strong brine. It can be condensed to a liquid at a moderate pressure, and its transmission in

carbide in the electric furnace is stated to be £4 per ton, ' feet, and the cost of the gas, therefore, works out at 6s. | yachts of a surprising variety of sizes and designs. 4½d. per 1,000 cubic feet. The gas won in this manner has, as stated above, an illuminating value of 240 candle power, and compares favorably in price with oil gas of 96 candle power costing 3s. 4d. per 1,000 cubic feet. It must be noted that the difference, which is about 9d. per 1,000 cubic feet, is not large, and would suffer change of sign if the estimated cost of manufacturing calcium carbide were found to be unduly low. The prospect of acetylene displacing other enriching gases must rest upon a better foundation before it can be termed immediate.

The handling and transmission of acetylene are attended by a curious risk. The gas has the property of forming compounds with several metals, such compounds-acetylides-being eminently explosive. Copper and brass pipes would be liable to yield copper acetylide from this action of acetylene conveyed through them, and to become coated with a detonating film. No similar tendency has been observed with the commonest materials for gas pipes, namely, iron, lead and tin. The precise methods that may prove to be feasible for distributing acetylene as an illuminating gas can only be foreshadowed. One obvious means consists in mixing the gas with air in much the same way as that used for "air gas," made by saturating air with the vapor of a light liquid hydrocarbon, liable to burn with a smoky flame. Some danger may Moissan has attend this course, as gross carelessness in adjusting enriched water gas. The addition of the acetylene could be effected either at the gas works or on the premises of the consumer, who would utilize a local reservoir of calcium carbide. In all these cases acetylene would of course compete with older methods of enrichment, and its cost of production is the only factor that need be seriously considered. Discussion pendent data than those quoted above being requisite for arriving at a valid estimate.

A better chance of putting acetylene to a practical use is afforded by the growing need in many places, sufficiency of water suggests numerous applications of this order. Lights of vehicles of all descriptions, inmight be replaced by calcium carbide and water, sig-

### New Forms of Ice Yachts.

Considerable time and money are being expended their decay; but all must admit and regret the shockthis form would not be more difficult than that of most this winter in testing new designs for improving the ing lack of general information upon this important other gases which are now commercially obtainable speed and efficiency of ice vachts. #### Mouth Hygiene.

The care of the patient's teeth is a matter too often neglected by the medical adviser, principally no doubt because of the important position the dentist now occupies in relation to every well-to-do family. The vast majority, however, of those seeking medical advice never go near a dentist unless for the purpose of having a root extracted. School children, the inmates of homes, asylums, prisons, and even hospitals are shamefully neglected in this particular. In most public institutions not only is the tooth-brush unknown. but it is almost an impossibility to secure proper cleaning of the teeth even in those taking mercury, for instance, where the danger of salivation is much increased by this neglect. Many institutions have gentlemen of the dental profession connected with their boards, but the teeth are much more apt to be overlooked than any other portion of the economy, and their every-day toilet slighted. It is, indeed, not an uncommon experience to find those who in health never omit the morning brush, go for days and weeks together without proper mouth cleaning when they are sick-the time above all others when the brush is most required. Of course, if the patient is too ill, an antiseptic mouth wash may replace it in a measure. A little volume of popular essays on the care of the teeth and mouth has just been published by Victor C. Bell, A.B., D.D.S., and we mention it here, not because of any new ideas or theories it embodies, nor because of its literary merit or beauty of illustration, for many things are more attractive than casts of irregular teeth and pictures of false sets. Such information as it contains, however, is most important for all to know, and if the advice given were followed, many a pain would be spared and many a tooth saved.

The proper care of the teeth of school children is receiving more attention in England than it formerly did, and no little credit is due to Dr. Cunningham, of Cambridge University, for his efforts in behalf of school children's teeth and his contributions on this subject to the Seventh International Congress of Hygiene and Demography, and his essay on oral hygiene, for which he was awarded the gold medal prize at the International Dental Congress held in Chicago during the World's Fair.

This gentleman says that parents and schoolmasters pay so much more attention to the quality of the child's food than they do to an efficient dental mechanism for its mastication, because of their ignorance of its importance and of the advantages, both economic and educational, to be derived from adequateattention to the teeth.

In speaking of tooth powders he says, "The principal action should be mechanical rather than medicinal. The power should be very finely grained and should contain no cuttle-fish powder, no powdered oyster shells, no pumice powder. It should consist of alkaline substances and contain no acid ingredients, nor such as are capable of changing to acid in the mouth. All fermentable substances such as carbo-hydrates are contra-indicated." He agrees with Miller, that precipitated chalk should form the basis of a powder, and also recommends a dash of neutral or slightly alkaline soap. He also considers a tooth soap preferable to tooth powder.

The physician needs not to be told how great is the necessity to the economy of sound teeth, nor need we enumerate the pathological conditions traceable to
