inch, at 4,000 yards; the "Iowa," 14 guns, at 2,500 yards; the "Texas," 13 guns, at 2,700 yards; and the "Oregon," 12 guns, at about the same range. The "Gloucester" was using five light rapid-fire guns. All of these, except the 13-inch guns of the "Indiana," were rapid-fire weapons, and the sea was being churned into a mass of foam about the doomed vessels. This being the case, it is certain that the value of the destroyer is not determined one way or the other by their destruction in the Santiago fight.

## Chained Libraries.

In a paper on the "Libraries of the Middle Ages."

buildings specially to hold their libraries were first erected by the universities and colleges. The oldest structure of the kind in England, perhaps in Europe, is the old library of the University of Oxford, which still retains many features of its original form. This structure, rarely seen by visitors and even unknown to the majority of Oxford men, is a two-storied building situated on the north side of the choir of St. Mary's Church, adjoining the tower at one end, and separated from the body of the church by a narrow courtyard. Having glanced at the way books were kept, used, and lent at Oxford prior to the erection of this building, the lecturer gaveasketch of its foundation by Cobham, Bishop of Worcester, about 1320, and some incidents in its early history, following with a description of the interior, furniture, and general ar-

rangements. Long desks were placed at regular intervals at right angles to the walls, on which the volumes lay on their sides. A bench was fixed in front for the reader, and a window came between each pair of desks to light that pew or cell. Every volume had a metal clip riveted to the front edge of the board forming one cover, to which was attached a light iron chain of the requisite length, having at the other end a ring. This ring ran upon an iron rod which was carried along the top of the desk, and was secured at the end by a hasp and a padlock to prevent the ring being drawn off. The foundation of Bishop Cobham's library was succeeded shortly afterward by that of the library of Durham College, Oxford, by Richard de Bury, Bishop of Durham (1335-45). The books bequeathed by De Bury to the college were kept for many years in chests, under the custody of scholars deputed for the purpose. At the beginning of the fifteenth century a library was built, and regularly furnished with bookcases or settles inclosing pews or studies between them where the books were chained. When

ham College still serves as the library of Trinity College. William of Wykeham's New College at Oxford set the fashion for all future collegiate buildings at either university in provision being made for every department, and thenceforward every college had its library as an essential part of its plan. Though books were few, the rooms devoted to them had to be very large, the chaining of the books to the desks making it possible to have only very few on each desk. Soon, as books increased, shelves were formed behind the desks, tier by tier, until at last, in the seventeenth or eighteenth century, they reached the ceiling. The appearance of the fittings before that time could be well seen in the old library of Merton College. Of chained libraries there were at least three extant in England, that belonging to Hereford Cathedral being the most ancient and perfect. Old chains, hasps, and staples belonging to Hereford - specimens of the actual fittings of a medieval

Trinity, and the old library of Dur-

chained library - were exhibited by Mr. Jackson, to smoke the least quantity in the longest possible another point of wide difference from the methods in use and the method of fixation explained. All Saints Church, Hereford, and Wimborne Minster also possess chained libraries. But the finest in the world is that of San Lorenzo, Florence, the great hall of which was designed by Michael Angelo in 1524, to contain the pensable tankards. The steward carefully weighs out collection formed by several generations of the Medici. The lecturer then touched on the difficulties of consulting books in the old chained libraries. Shelves for the ever-increasing number of books had been provided, but desk accommodation remained as before. One student occupied on a volume prevented three or four others getting access to the books. This led to fire in his bowl as long as possible and to consume the the library rooms being enlarged. Chains were bought smallest possible amount of tobacco. A member whose for the Bodleian Library as late as 1751; it was not pipe goes out drops out from the contest, and only his

till 1757 that this method of securing the books was more fortunate or more skillful rivals are allowed to abolished.

### Bog Iron Ore in Canada.

Bog iron ore is worked in the province of Quebec, and arrangements are being made to extract manganese from bog ore deposits in the province of New Brunswick. The ore is a soft, wet stuff, containing 50 per cent of water, and is covered by a thin coating of vegetable earth. The depth of ore varies from 5 feet to 30 feet. When dried the residuum is a fine black powder. too fine to be treated in the blast furnace, and this has therefore to be made into briquettes, as is done with recently read by Mr. T. G. Jackson before the Royal the fine dust from blast furnaces and the finely divided Institute of British Architects, the lecturer said that iron produced from low grade ores by the Edison elec-Russia over the Caucasus Mountains into the pro-

## A Flemish "Smoker."

According to L'Illustration, the nineteenth century citizens of Bruges amuse themselves much after the fashion of the contemporaries of Van Maerlant and Van Artevelde, those great drinkers and smokers of the thirteenth and fourteenth centuries. In this quaint old Flemish city there exists the "Brugsche Rookersclub" or Smoking Club of Bruges, the members of which assemble to enjoy one another's society, to smoke their long clay pipes, and to drink their flagons of beer.

Every evening, it seems, the Rookersclub has a smok-Durham College came to an end at the Dissolution, its ing contest, each member endeavoring to consume not old buildings were utilized by its successor, the present the greatest quantity of tobacco in a given time, but tined wooden forks to permit the kernels to fall to the

A BREAD BAKERY IN RUSSIAN ARMENIA.

time. Before the contest begins, the vice-president and steward of the club seat themselves before a table on which are placed a balance, a tobacco box, and a number of long-stemmed pipes, not forgetting sundry indistwo grammes and a half of tobacco, and methodically the vice-president stuffs each pipe with its allotted quantity. The pipes are then distributed among the contesting members. At a given signal, each contestant lights his pipe and begins to smoke, very slowly and very deliberately, endeavoring to keep alive the

continue. When pipe after pipe goes out, or the tobacco is consumed, the contest becomes more and more interesting; and when only two contestants are left, the most intense excitement is aroused.

So expert have the members of the Rookersclub become, that they have been known to keep alive the flame in three grammes of tobacco for a period of an hour and a half. W. B. K.

## PRIMITIVE METHODS OF RAISING WHEAT AND BAKING BREAD IN TRANSCAUCASIA AND ARMENIA.

As soon as the average traveler passes from European

vinces of Georgia and Armenia, which have been parts of the Russian empire for only a comparatively short time, he feels that he has entered a strange part of the world, the tnanners and customs are so different from those which prevail in western Europe and America. Nowhere is this more clearly brought out than in the methods pertaining to agriculture and bread making. The farmer still uses the implements which his ancestors used and he handles them in the same manner. In the spring the ground is scratched up by means of a clumsy wooden plow drawn by buffaloes or oxen, very rarely by horses, and the grain is scattered over it by hand. The writer was in Transcaucasia and Russian Armenia during the harvest season last year, and had the opportunity of making the photographs accompanying this article, which illustrate the methods of thrashing

near Erivan, the capital of Russian Armenia, we saw the wheat spread out two or three feet deep over a small area of specially prepared ground. Cattle, both oxen and buffaloes, were driven around and around on the grain until the kernels were all broken out of the heads. The biblical injunction is not obeyed here, for the photograph shows that the driver has "muzzled the ox which is treading out the grain."

A more common manner of thrashing is that shown in the picture from Jélénovka, on the shores of beautiful Lake Goktchai. Here there was a very large thrashing floor and an instrument like one of our stone sledges was dragged about over the grain by means of a team of horses. The bottom of the sledge was armed with numerous small pieces of rock, set so as to present a sharp edge for the cutting and mangling of the grain heads and straw as the sledge was driven about. The use of horses for this work, however, is not common, buffaloes and oxen being much more often employed. When the grain has been broken out of the heads, the straw is shaken up with two-

> ground. Then the straw is removed, to be mixed with cow dung and dried to form the national fuel, and the winnowing process begins. A day with a gentle breeze is chosen, and the grain and chaff are thrown up into the air by means of longhandled wooden paddles. The wind blows away the chaff, while the wheat falls back to the ground. In Sémenovka, as is shown in our engraving, we saw the grain spread out on skins kept for the purpose, where it is stirred and turned until it is well dried. There seem to be no steam engines in Armenia and windmills are unknown, but the scanty water power is well utilized for the grinding of the grain, and there are numerous mills at Tiflis, Erivan, and elsewhere. Those at Tiflis are an interesting feature of the view from the principal bridge over the swift Koora. They are worked by means of great undershot wheels, and the whole mill is moored out in the stream at the best place for getting the full effect of the current with safety.

The baking of the bread furnishes in America. The oven is usually (at least outside of the cities) a hole in the ground three or four feet deep and as many in diameter, narrowing toward the opening in the top. It is lined with pottery or even with nothing but hardened clay, and a wood or charcoal fire is built in the bottom to heat it. The dough is mixed in a trough, formed then into balls with the hands and afterward rolled out on a circular or oval stone or board, until it becomes a sheet about three feet long, fifteen inches wide, and one-eighth of an inch thick. This sheet is carefully spread out over a form like a pillow of the proper shape. The pillow is dexterously seized underneath by the baker, who then bends down into the oven and spats the dough against the wall, where it sticks and is baked in a very few minutes. twigs well preserved, they even sprinkle them with that case it must be returned to the sender, who has to The sheet is then pulled out by means of a hook and water before wrapping them up, which not merely pay double rate for it if he accepts it; but he, too, may is hung on the wall of the shop to cool and dry. At increases the weight at the time of mailing, but also refuse it, and then its final destination will be the several places in the city of Erivan these thin sheets serves to spoil the wrappers. Christmas time and Dead Letter Office, in Washington, if the letter originare baked on beds of hot pebbles. This literally Easter, when friends interchange gifts, are equally ated in the United States. The United States gets "whole wheat" bread contains no salt and re-profitable in this respect; but the United States does nothing for all this trouble. Occasionally there ap-

sembles pieces of brown paper in appearance, but it tastes better than it looks and is inexpensive, the price in Erivan being only six kopecks (about 3 cents) per kilo  $(2\frac{1}{5})$ pounds). The customer receives it without wrapping paper and carries it off in a roll under his arm or in his hand. Another form of loaf is put into the same kind of an oven as a cake, ten or twelve inches in diameter and two inches thick in the middle. This comes out as a curiously distorted affair, on account of the sagging which takes place before the loaf gets hard and which thickens one side while it thins the other, making it look somewhat like a lady's hand bag. The foreigner will prefer to eat this or any other kind of bread without butter, because that which is indigenous to the country has been churned in a goat skin with the hair turned in, and is anything but attractive in appearance or odor. A peculiar substitute for butter is the cream from buffalo milk. This, too, would never

find favor in western eyes, because it is too much like not collect as much on foreign mail as the foreign varied an experience as it is possible to obtain in tallow in appearance and consistency.

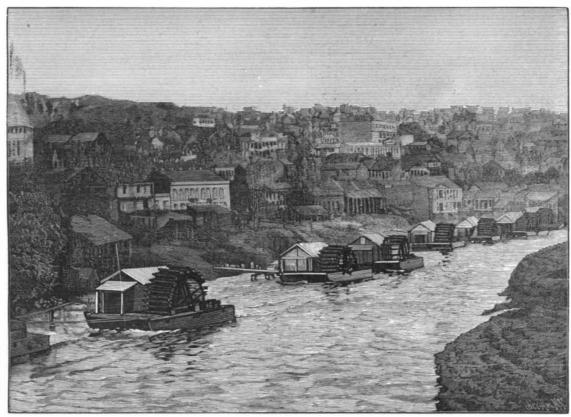

## Mail Service "Mysteries."

Less care is used by the people in America than by for service they do not perform, says The Boston sent abroad every week, and when it arrives at the point of delivery it is rated up to doublethe deficiency. About two hundred souvenir postal cards, for instance, addressed to people in Germany, were mailed recently, and there was only a two-cent stamp on each

postage is five cents, the same as for a letter. Had the sender been known to the post office men, he would have been notified, but in this case each card had to be stamped with a "T" to indicate that postage was not fully paid, and then forwarded, because the sender, a Cambridge person, had signed his initials only, and could therefore not be found. When these cards arrived in Germany the equivalent for six cents, just double the deficiency, will be collected for each card. Thus the German government will receive three cents on each card for nothing.

This kind of mail is a good deal larger than is generally supposed, as is shown by the fact that \$100 may be collected at the Boston office on one single mail from Europe, and the United States sends about fifty times as much as it receives. Most of the unpaid or shortpaid matter comes from Armenia and Turkey, although England and Ireland contribute a fair portion of it. Just before St.

Patrick's Day the mails are flooded with packages offender. It is a matter of principle with some indi-northern form; and the latter appears to range all of shamrocks from Ireland, picked and mailed by viduals to refuse underpaid matter, says one who is in a across the Sahara into Northeastern Africa. people who know little about the postal regulations, position where he sees refused letters when they return. and who frequently neglect to find out how much A letter may be sent to some foreign country without postage is required. Anxious to have the precious any postage on it; the addressee may refuse it, and in 36,000,000 miles away.

GRIST MILLS IN THE KOORA RIVER AT TIFLIS, TRANSCAUCASIA,

governments collect on United States mail.

There is such a wide difference in the amount collected by the various nations that years ago it led to negotiations for new regulations, resulting in the adoption in this country of the "due stamp," and now those in European countries in the preparation of mail each government keeps the money it collects for due matter, and as a result the United States government postage. Those due stamps serve, in reality, merely is losing money, while foreign governments get paid to show how much is collected, as they are put on and canceled in the post office, and no person connected Transcript. Short-paid matter in large quantities is with the service can by honorable means obtain one that has not been canceled. In spite of the law, such would go for two cents each, but since they are postage. If an attempt were made to use it, post office

stamps have come into circulation, probably through burglars who have broken into post offices or through dishonest postmasters; but it matters little to a private citizen how he has obtained such a stamp, whether he card. If they were regular government cards, they has paid for it or not, for the stamp is not acceptable as

pears a postal card that is evidently traveling around the world to gather postmarks for its sender. But the United States proposes not to be imposed on to that extent when it can help it, and if it sees the scheme it will put on a mark that ends the postal card's mission.

Counterfeit postage stamps were in circulation in the United States a few years ago, but what has become of them or to what extent they were used is not known. They were such good copies of the two-cent stamps that only an expert could detect the difference. As a guard against them the government secured a large amount of them and sent sample sets to the large post offices in the country to be used for comparison. The set that was sent to the Boston office is still preserved there, but it has never been used, as no counterfeit stamps have been seen passing through that office.

It might be expected that in an office as large as the Boston post office the postal employes have about as

the postal service, but when the mail from "La Champagne" arrived at the Union Station the other day the three men that were sent down to receive it saw a sight that had not presented itself before in Boston postal experience-a conglomeration of foreign mail sacks containing mail made up for places that were almost unheard of here, as the general foreign mail for the West and South is not sent to Boston, but goes to New York.

# Concerning Giraffes.

The young male giraffe from Senegal lately acquired by the Zoological Society of London, and now domiciled in its garden, is of special interest, says Nature, "as representing the northern form of this animal in contrast to the southern female which arrived in February, 1895; but the differences between them will be much printed by a private concern and are written upon, the inspectors would be at once put on the trail of the more apparent when both specimens have fully reached

adulthood."

Although the northern giraffe has, by various authors, been considered to differ considerably from the southern form, and several technical titles have been proposed for, or given to, each, the subject for the first time has been placed on sound zoological basis by Mr. W. E. De Winton, in a paper read before the Zoological Society, in February of last year, entitled: "On Existing Forms of Giraffe." Mr. Winton conclusively demonstrated that the northern form is distinguished from its southern relative by several characteristics, especially by the great prominence of the third frontal horn, which is barely existent in the latter. He proposes to restrict the title "Giraffa camelopardalis" to the northern giraffe, bestowing upon the southern variety the specific designation of "capiensis." The Cape giraffe seems to be met with in suitable localities all up the east coast into British East Africa. where it also meets the

In connection with this congress, there will! The exhibitors are not put to any expense, the exhibitor devoted to machinery, including shaping be several exhibits, one of scientific apparatus, one tion committee undertaking to pay all freights and the and polishing machines, forging presses, and engines, of scientific photography, and one illustrating the cost of fire assurance. The exhibition, which is located history of medicine and science. The last will be in the Kunstgewerbe Museum, was opened in July, and Hundred Years of Ginning and Baling Cotton" is an exhibits will be received up to September 15. The example article by Mr. G. A. Lowry, describing the old methods

### Duodecaplex Telegraphy.

Experiments are at present being conducted on the Paris-Bordeaux line with some very interesting machines, which the inventor, M. Mercadier, has been working on for many years. With these instruments, called duodecaplex, twelve Morse transmitters can work simultaneously on a single wire, each sending its signals to the proper receiver at the end of the line. This result is brought about by the use of alternating or, at any rate, interrupted currents.

Each transmitter receives its current through a tuning fork having a special note, its vibrations being electrically maintained. These vibrations furnish a current of the proper period to cause resonance at each application in the proper receiving circuit, which has its self-induction and capacity adjusted for this result. This receiver is a telephone (a monotelephone, as it is called by M. Mercadier) so constructed and arranged that the acoustic resonant qualities also help to damp out from the signals received everything not intended for it. These signals are read in the ordinary way by ear, aided by rubber tubes like those used on phonographs. The sifting out of the signals, it seems, is very perfect, each receiver giving no evidence of those signals not intended for it except a slight murmuring very indefinite and not at all bothersome.—Electrical

# RECENTLY PATENTED INVENTIONS.

## Electrical Appliances.

BATTERY-ELECTRODE.-HENRY E. WILKINSON, Mount Vernon, O. This invention is an improvement in grids or battery electrodes. The improvement provides a main or central plate and a pocket-plate secured thereto, having pockets formed with front sides which slope inwardly toward its bottom, and with ends arranged at angles to these front sides and converging downwardly. The active agent may be applied to the pockets in any suitable manner, and when thus applied is freely exposed to the action of the electrolytic liquid.

TELEPHONE-TRANSMITTER ARM AND AT-TACHMENT.-WILLIAM J. BARR, Ashtabula, O. Hitherto, telephone transmitter-arms have been pivoted or hinged to a hase adapted to be secured to a wall or other base is provided with one or more integral trunnions. The transmitter-arm is detachably secured to the trunnions by means which insure a firm joint at all times and vet permit easy disconnection of the arm when required, The transmitter cup is integrally constructed with the arm. Economy in manufacture is one of the advantages claimed for this improvement.

# Bicycle Improvements.

BICYCLE-SUPPORT. - ABRAHAM W. LEWIS, AS bury Park, N. J. In this improved bicycle-wheel holder a curved bar is provided, vertically arranged and pivoted to a fixed support at the middle of its length, so as to rock and be capable of adjustment. A pair of clamping rings is arranged at the middle. At the end of the bar, bifurcated lugs embrace and hold the wheel rim.

BICYCLE CRANK-SHAFT.—SAMUEL A. DONNEL-LY, Chicago, Ill. The drive shaft provided by this in-Cones there are, with one or more recesses or wings, with a downwardly-extending flange, toothed at one such recesses or wings permitting the cones to pass from face and adapted to engage one side of a joist or like suptheir seats over the wide back-stop and all exterior port. A lever is fulcrumed on the frame and carries a the cranks is to reinforce these ends, so that they will studs are subjected. Unlike the one-piece cranks com- a spring pawl. A segment forms an integral lateral exaxle section, because the cone having the recesses to provided on its under surface with a guide engaging a pass over, the widened section on the crank-axle can also segmental recess on the under side of the toothed sega ready adjustment of the cones.

BICYCLE STEADYING DEVICE.-FRANK BARTO. New York city. The purpose of this invention is the provision of a new and improved bicycle-steadying de- joist. vice, arranged for convenient attachment to a bicycle and adapted to hold the front or steering wheel normally in proper alinement with the rear or driving wheel. Provide a machine so constructed that it will remove the The rider may turn the front wheel in any position and return the wheel to its alined position whenever the ears to an elevator, whence they are delivered to a he releases the pressure on the handle-bars, after steer- wagon traveling alongside of the machine. In this maing the bicycle in the proper direction, tion comprises principally clamps of special construc-tion, which are secured to the members of the front fork, springs connected with the clamps, and a clip held ad- extend over the forward ends of the rollers. Feed-belts justably on the lower brace of the bicycle frame and travel along the inner faces of the shields and a trough apparatus is designed to draw wine, ale, or liquids likely adapted to receive the rear ends of the springs.

## Mechanical Devices.

WINDOW RAISING AND LOCKING DEVICE,-FRANS BRUNO, New York city. The purpose of this invention is the provision of a simple mechanism, comprising a spring-motor that will be automatically wound up or set by a downward movement of the sash mechanism dispenses with the usual weights. The device comprises a rack on a window-sash, a spring-opegear-wheel to engage with this rack, a frame in which the wheel is mounted, and a pivot extended across a mortise in the window casing. This pivot passes through a holeat the upper portion of the casing arranged in the mortise, whereby the lower portion of the frame may be swung wholly out of the mortise. When the wheels are allowed to rotate, the springs will operate the wheels, and the rotary movement thus produced will raise the sash by means of the racks. When the sash is fixed support. In the present improved attachment, a moved downwardly, the wheels rotate to wind the springs, thus placing the springs in proper tension to open the window again.

ILLUSION APPARATUS. - ATTILIO PUSTERLA, New York city. This invention provides an apparatus which produces on spectators the impression of traveling on land or water. In this apparatus, moving cenery is provided which comprises a number of sections or strips, supporting pulleys or disks of different diameters over which the strips pass, intermediate supports for the strips having individual supporting devices for the central portions of the strips, and means for moving the strips. The distance between the strips gradually increases from the center toward the disks, thus obtaining a better effect of objects receding into the distance.

FLOOR-CLAMP.—EDWIN C. INGERSOLL, Philadelphia, Pa. The floor-clamp provided by this inventor is more especially designed for the use of carpenters to ventor has integral with it opposite end cranks, and also force a loose floor board conveniently in engagement has seats for the cones and a back-stop between the with the one already fastened to the joist, so as to facilicones of greater width or thickness than the cone-seats. , tate nailing the board in place. The clamp has a frame parts. The purpose of the enlarged, flattened ends of depending jaw at one end adapted to engage the opposite side of the joist, at a point opposite the torward end of not spread by reason of the strains to which the pedal- the toothed flange. Near the other end, the lever carries monly in use, the crank-ends in this invention, it is ob- tension of the frame, and is provided with teeth on its served, may be enlarged to the size of the widened crank- upper face to engage the pawl. The lever is further pass over the enlarged ends of the crank. By this con- ment, whereby the lever is held against up-and-down struction of recessed cone and enlarged crank ends, a 'movement. The frame has a guideway and a bar carrystrong and durable construction is secured, that permits ing a presser foot, adapted to slide in the guideway. This guideway is located at the outer side of the toothed flange and parallel therewith, whereby the presserfoot engages the board to be nailed at one side of the

> SEM. Paullina, Ia. The object of this invention is to ears from the standing corn, husk the ears, and convey The inven- chine a supporting frame is connected with inclined snapping and husking rollers mounted in the frame and having spirally grooved forward ends. Converging shields is carried on each side of the feed-rollers. In the bottom

leads. In operation the standing corn is received between , a barrel containing the liquid to be drawn. An airthe snapping and husking rollers, the feed belts assisting the corn in its passage to the rollers and giving the corn inclined position of the rollers serves to draw the stalks downwardly and rearwardly, thus snapping the ears from will be stripped from the ears, and the cleaned ears are delivered by the rollers to either trough and from thence to the elevator, from which the corn may be dropped into a near-by wagon.

Co

D١

flance, O. In this invention novel means are provided for roughly-prepared balls, the latter were hitherto kept in punching D. shaped openings in handles for shovels, forks, circular grooves and in describing always the same circuand the like, the arrangement permitting the opening to be lar line, they were worked either upon a flat grindingformed by one operation in a very simple and effective manner. The punching tool is carried on a frame. On this finely toothed guide grooves or in such a manner that the frame a bracket-shaped slide is mounted to move ver- balls were ground in oil and emery between the smooth tically, and is provided with a horizontal portion having an opening. A chute is attached to the bottom of grooved themselves or the disks inclosing the grooved the horizontal portion of the slide and surrounds the opening to conduct the chips therefrom, A U shaped ing it necessary that the grooves corresponded to the projection straddles the chute and is attached to the size of the ball. In the present invention, a frame is horizontal portion of the slide. There are means in connection with the projection by which to impart reciprocal movement to the slide. A holder is mounted on slidshle and revoluble and is connected with a lever enthe horizontal portion of the slide and has a central opening registering with the slide opening. The holder also capable of holding the lever raised out of engagement has a horizontal guideway in its top face. Plates are with the cam. The balls introduced into the machine mounted to slide toward and from each other in this are rapidly and uniformly distributed around the revolvguideway. Clamping jaws attached to the plates hold the ing stamp, and itis not necessary to place them as formerly work between them. Means are provided for moving : -circularly into the grooves. Not only a single row, but the plates toward and from each other to grasp and release the work,

LOCK FOR FLUSHING-VALVES.-CHARLES H. SHEPHERD, New York city. By means of the lock patented by this inventor, a raised flushing-valve lever may be set to lock in position until the tank is empty and the gioves and similar articles, but adapted as well to secure lever is released by the float-lever unlocking the lock. The lock comprises a lever-arm arranged to connect with sists of stud and socket members. The socket member a flushing-valve lever, a shaft carrying thearm, a toothed wheel on the shaft, and a spring-pressed lever-pawl to engage the wheel and lock the latter in position against lar apertures disposed along the line of strain and prorotation in one direction, the lever-pawl being adapted jections on the body at opposite side edges of the aperto be actuated from the float-lever of the tank to unlock the wheel and lever-arm.

BELT-REGULATOR .- OSCAR K. SLETTO, Fergus Falls, Miun. This belt-regulator is adapted for use upon , adapted to enter the apertures. threshing machines and their driving engines, and is so . FOLDING UMBRELLA. - FRANK G. GROVE and constructed that the guide-pulley or idler may be vertically and laterally adjusted relative to the driver pulley. of these inventors is considerably simplified in its frame-The device is furthermore designed to prevent the belt vibrating in the wind, thus avoiding side-wear, and causing the belt to run true and without undue CORN HARVESTER AND HUSKER.-John TJos- | friction. The belt-regulator comprises a hanger provided with a tubular section having exterior teeth, a frame mounted to revolve upon the tubular section of the hanger, a pawl carried by the frame and arranged for engagement with the teeth of the hanger, a guide-pulley | hold the runner when the umbrella is closed and which mounted on the frame and adjusted by means of a latch carried by the guide-pulley support and adapted for engagement with the teeth of the hanger.

> APPARATUS FOR DRAWING LIQUIDS.-ALEX. RITTER, Basle. Switzerland. This new and improved to foam or leave sediments, without disturbing the sedi- | Ill. This computing scale is designed to indicate both

> of the troughs conveyer belts are located. One of the ment and rendering the liquid cloudy. The apparatus troughs empties into a hopper from which an elevator has a receptacle with a valved inlet for connection with the shields and by them is directed so as to pass between pressure inlet-pipe opens into the valved inlet to close the valve therein, to interrupt the communication between the barrel and the receptacle and to permit the air a rearward inclination before it meets the rollers. The to flow into the receptacle and force the liquid to the fancet. This faucet has a connection with an air-pressure supply, with the air-pressure pipe and with the the stalks. The basks being caught between the rollers lower end of the receptacle to connect the air-pressure supply with the air-inlet pipe at the time the faucet is open, so that the air-pressure forces the liquid from the receptacle to and through the faucet.

MACHINE FOR WORKING BALLS. - HEINRICH PUNCHING MACHINE.-CHARLES SEYMOUR, De. MELTZER, Ratibor, Prussia, Germany. For working disk or this working was effected by the walls of the walls of the groove. The result was that the disks guide-plates were moved in opposite directions, renderprovided with which a bowl is connected. A stamp coacts with the bowl. A spindle attached to the stamp is gaged by a cam. An arm is pivoted to the lever and is several rows of balls may be worked simultaneously.

### Miscellaneous Inventions. FAS'TENER .- CHARLES V. WALTER, New York city.

This fastener is particularly adapted for use in securing any article having overlapping flaps. The fastener concompris es a plate having its edges flanged or curve inward and under, and a plate having a scries of rectangutures. These projections are bent over so as to clasp and hold the stock and the inwardly flanged members of the other plate. The stud member having a side projection

FRANK E. STOVER, Luray, Va. The folding umbrella work. Its telescopic ribs are so constructed that when drawn out to their full length and the runner carried upwardly on the stick, the action of the contracting portions of the two ribs will be such as to hold the ribs immovable and render the telescopic or sectional ribs as strong as a one-piece rib. The folding stick is provided with a spring at its lower section, which is adapted to may be conveniently placed therein. This spring serves to limit the movement of the lower section of the stick and lock this lower section either when drawn from the upper section of the stick or when carried to an engagement with that section.

COMPUTING SCALE.—CLARK CORBIN. Carbon Cliff.
