### THAT ATHBARA BRIDGE CONTRACT.

Further particulars that have come to hand regarding the letting of the contract for the Athbara bridge in the Soudan to an American firm, are of great interest as showing the rapidity and cheap cost at which our bridge companies can undertake to lay down material, as compared with foreign competitors. Late last year the British government decided to complete a railroad bridge across the Athbara River, a large tributary of the Nile that is intercepted by the military railroad now building through the Soudan. It was determined to complete the bridge before the floods of July, 1899, or within a period of six or eight months. The designs and specifications were drawn in London and bids were solicited from both British and American firms. The American bids varied from \$52 to \$65 per ton and the time of delivery was in each case two months and a half, while the lowest British bid was \$68 per ton and the highest \$80.50 per ton, the time of delivery varying between three and a quarter months and six

When the design and the bids were received in Egypt on December 28, it was discovered that the bridge, as designed, did not admit of being launched from the piers, but would have to be erected on false work. The character of the river was such that it would have taken two years instead of six months to build the bridge upon false work. As time was a matter of supreme importance, a telegram was sent to the two English firms that had promised the earliest delivery, asking how soon they could supply a bridge of a type suitable for launching, and promising a premium for early delivery. It was found that no supply could be obtained under six months. Inquiries were also made in America as to how soon a bridge of standard American design could be supplied, and a wire was at once received that a bridge could be delivered on board at New York in six

A contract was signed on January 30 of this fear; the seven spans were completed in thirty-seven cavs. or five days earlier than the contract date of March 8, and the complete bridge was on its way to Liverpool by March 15. It was due at Alexandria about April 15. and it is expected that it will reach the site by May 15, or a few days before the piers have been completed. The structure will be bolted together temporarily for launching across the piers, and riveted up subsequently. It is now probable that the whole bridge will be in place by the first day of July, when the Nile floods are expected. It will thus be seen that the expeditious methods of the American firm will enable trains to be running across the Athbara River one month earlier than the English builders could have placed the material on board ship in an English port. Comment on these very remarkable comparisons is unnecessary.

### WIRELESS TELEGRAPHY ACROSS THE ENGLISH CHANNEL.

The recent experiments of Marconi in telegraphing without wires across the English Channel have entirely removed his work from the region of mere experiment and established it among the practical and extremely useful inventions. The main facts of the recent test are already familiar to our readers and require no reiteration here, but we wish to draw attention to the fact that we publish in the current issue of the S IPPLEMENT illustrations of the terminal telegraphic station at Wimereux, on the French coast, which cannot fail to be of extreme interest. One of the photographs from which the illustrations are made shows the terminal steel mast or rod with its guys in position, erected on the beach in front of a small villa. in one of the front rooms of which the receiving and transmitting apparatus is located. Another of the photographs shows the interior of the room and two of Marconi's assistants engaged in receiving a telegram from the English coast, thirty miles distant. Messages are dispatched with perfect freedom from the vertical mast on the French coast to that on the English coast. and vice versa. At the time that the photograph was being taken the "Cassini," with M. Lockroy, Secretary of the French Navy, on board, passed down the Channel within view of the French coast. The assistants on

noticing the ship transmitted the news across the Channel, and in less than a minute a reply was received, "If the secretary comes to see you, give him a good reception." The Morse receiver is used, and the message is written on the tape in the usual dots and dashes of the Morse code. In view of the large amount of visionary speculation that has been indulged in by some of the investigators of wireless telegraphy, there is something decidedly refreshing in the businesslike methods and practical results which have characterized the work of this brilliant young Italian.

#### SINE-WAVE TELEGRAPHY.

The system of sine-wave telegraphy invented by Messrs. Crehore and Squire was recently made the subject of a long-distance test, in which the remarkable feat of transmitting 120,000 words an hour was accomplished. The experiments were carried out under the direction of Gen. Greely, chief of the Signal Service, between Fort Myer, Virginia, and the War Department, Washington. Kipling's celebrated poem, 'The White Man's Burden." was transmitted back and forth continuously between these points for the space of an hour, and it was found that the total number of words dispatched was 120,000, a rate of 2,000 to the minute. In the matter of speed and distance, this test has been exceeded by one carried out by the inventors in October, 1898, when they reached a speed of 3,000 words a minute over a cable between New York and Canso, Nova Scotia.

The sine-wave system makes use of the regular telegraphic wires. The telegraphic characters are punched in a paper tape, similar to those used in the stock tickers, and the tape is fed to a transmitter, which, by an ingenious application of the principles of the alternating current, sends messages with extraordinary rapidity to a polarizing receiver, in which, by means of a rotating photographic plate, the message is reproduced. At the time of the earlier experiments we devoted considerable space to the subject, and the reader is referred to the SCIENTIFIC AMERICAN SUPPLEMENT for May 8 and 15, 1897, and March 19, 1898, for complete illustrations of the apparatus, and a lengthy description by the authors of the system.

### OFFICIAL TEST OF THE NEW ARMY WIRE GUN.

The United States army is testing the wire-wound principle of gun construction on a scale and with a thoroughness which will settle the value of the system one way or the other to the satisfaction of all parties concerned, whether lay or professional. The trials, as far as they have gone, are strongly in favor of the system, and unless some mishap occurs before the specified number of rounds has been fired, the army will be in possession of fifty of the most efficient guns, for their weight, in this country, and certainly the strongest guns that have ever been turned out in the history of the art of gun construction.

One of the chief objects of constructing guns by shrinking hoops or winding wire upon an inner tube is to throw all the metal of the gun into a condition of initial strain, or in other words, to compress the interior metal and stretch the exterior metal. By thus wrapping the metal tightly around the bore, as it were, the pressure of the powder at the instant of firing is felt and resisted by every particle of metal in the gun. In a finished built-up gun the metal at the bore is in compression, and that at the circumference in tension, the strains passing from compression to tension, with a neutral point somewhere midway in the body of the metal. The greater the compression at the bore, the stronger the gun, other things being equal. There is a limit, however, to the allowable compression, for if we shrink the hoops or wind the wire too tightly, the metal at the bore will be injured. We must not compress it beyond its elastic limit, and hence we see that the strength of the built-up gun is primarily dependent upon the elastic compressive limit of the metal at the bore. In the common type of built-up gun the core upon which the hoops are shrunk is a forged tube of steel; and while it is possible by careful work in forging and tempering to bring the steel up to a high standard of elastic compressive strength, this tube steel does not by any means represent the highest elastic limit that can be produced by special methods of work on steel in other than tubular shapes.

It occurred to Mr. J. H. Brown, the inventor of the wire gun now under consideration, that if a tube were built up of separate longitudinal segments, it would be possible to subject them to a cold-drawing process and secure the extraordinarily high elastic qualities which result from cold work. Under his system a number of flat tapered bars of open hearth steel are cold-drawn to such a width, thickness, taper, and length, that when assembled and clamped together they form a tube answering to the forged tube of the ordinary gun, but possessing vastly greater qualities of resistance. Upon this segmental core the wire is wound at a certain tension, until the desired degree of compression of the core is reached. The core serves merely to receive and carry, as it were, the accumulated tension of the successive windings of the wire, so that when the gun is fired the pressure may pass through the core

(which, of course, has no power of tangential resistance) and be immediately resisted by the wire. The high quality of steel that can be secured in this type of gun was shown in the tests of the metal put into the first gun of the type tested by the army officials, the segments showing an elastic strength of 126,000 pounds and a breaking strength of 176,000 pounds to the square inch, while the respective figures for the wire were 230,000 pounds and 262,000 pounds to the square inch.

The excellence of this system of construction is shown in the ballistic figures of a 5-inch segmental gun tested a few years ago at Sandy Hook with brown powder, when 216 rounds were fired with abnormally high pressures and velocities, which reached in the 157th round a maximum of 82,600 pounds pressure in the powder chamber with a resultant velocity of 3,235 feet per second. A 10-inch experimental gun was then ordered by the army and is to be tested this summer. and this was followed, in 1898, by an order for twentyfive 5-inch and twenty-five 6-inch rapid-fire guns on the same system. The terms of the contract for these guns require that they shall develop a velocity of 2,600 feet per second with a maximum chamber pressure not to exceed 45,000 pounds per square inch. The first or "type" gun is to be fired as many rounds as will develop the same amount of scoring as would result from 300 rounds with the old brown prismatic powder.

The first one hundred rounds have recently been completed by the government officials, and an extract of the highly satisfactory firing-sheet is herewith pre-

OFFICIAL TEST OF 5-INCH SEGMENTAL TUBE WIRE GUN.

Round.	Powder Charge. Smokeless Powder.		Muzzle Velocity.	Pressure per Square Inch of Bore.
	Lb.	Oz.		
1 2	10 12	-:-		*18,000 lb. 21,050 "
3	15		2,705	32.800 "
4	16	٠	2,821	35,750 "
33	14	6	2,601	30,000 **

\* Should read less than 18,000 lbs.

In the first few warming-up rounds the pressure was run up from less than 18,000 pounds toward the maximum of 45,000 pounds, but at 35,750 pounds the velocity was already 221 feet above the contract velocity, and the powder charges were gradually reduced to 14 pounds 6 ounces of the new army smokeless powder at the thirty-third round, which gave a fairly constant velocity of 2,600 feet for a pressure of about 30,000 pounds in the chamber. The last five shots will be fired at between 45,000 and 50,000 pounds pressure, under which a maximum velocity of between 3,200 and 3,300 feet per second may be expected.

### WHAT OUR CONSULS ARE DOING FOR AMERICAN TRADE.

We have, on another occasion, referred to the great value of the reports of the United States Consuls, and it seems that their enterprise is leading to trouble in Germany. The American Consul at Leipsic requested the Chamber of Commerce of that city to furnish him with certain information concerning the preparation of rabbit's skin for the hat trade. 'The Chamber replied that, although it was desirous of promoting the trade of Germany with foreign countries, it must, as a matter of principle, decline to furnish technical reports on German manufactures that would be likely to assist foreign competitors. The Leipziger Faerber Zeitung published the following, headed "Unfair Competition! Industrial Espionage by the Consuls of the United States." The article goes on to say: "It was left to the present administration of the 'Great' republic on the other side of the great lake to degrade a government's commercial agents to industrial spies. A report of Consul-General Frank H. Mason, of Frankfort-on-the-Main (formerly at Chemnitz) begins with the following significant words: 'I have the honor to confirm the receipt of the special instructions of the department in which I was ordered to give, in a report, such detailed information regarding the production of the tar-dye-stuffs as would enable an experienced chemist to manufacture such dve-stuffs in America.' The poor Consul, after considerable spying, had to sit down and write a report, which we may be spared from reprinting. But it says therein quite correctly, 'It is useless for anyone, even an expert, to obtain from a German factory or laboratory secret information on the substances and processes which the owner of the process desires to keep secret.' Our government should send all Consuls who are caught at such vulgar espionage their passports at once."

A Hanover paper says, "The American Consul's practice of mixing in Germany's inmost concerns is becoming systematic." A papermaking trade journal states that a Consul who desired information on papermaking was even more inquisitive than the statistical department of the ministry of the interior. Anti-American papers all over Germany are making an en-

# Scientific American.

ergetic campaign against the consular inquiries. They have to admit, however, that the reports of the American Consuls are most valuable, and they regret that German Consuls do not show the same enterprise. Naturally the German manufacturers are the first people to take exception to the splendid work which our Consuls are doing, for we are rapidly competing with Germany in many markets which she formerly held as her own. We hope that our Consuls will be able to continue to carry out their good work and that the value of their reports will not be impaired by refusals to give information.

These reports have become so far recognized as being of great value to our manufacturers that we publish the shorter and more important of these reports weekly in the SUPPLEMENT of the SCIENTIFIC AMERICAN, and we also publish a weekly index giving a complete list of all the reports issued by our Consuls.

### AMERICAN MACHINE TOOLS IN ENGLAND.

----

Our esteemed contemporary, Industries and Iron, of London, has this to say regarding the increasing importation of American machine tools into England, and the causes therefor:

"It is in one sense gratifying, though not in another, that such a brisk trade is being done in this country with the United States in the importation of automatic machine tools. This trade is increasing day by day, since each machine acts as a kind of advertisement for another. Standard patterns and tools that do the most work in the least time, and at the least expense, are mainly accountable for the inroads which have recently been made to the prejudice of the engineering trades of this country. The recognized superiority of America in class tools is unreservedly recognized, though hypotheses vary as to the causes which have brought about this distinction. The general, though as we think erroneous, impression is that these highly elaborated machines have been brought to their present state of perfection through the absence in the States of what is commonly termed "cheap labor." We do not accept this as a tenable theory. Owing to circumstances, the inventive faculty is far more strongly developed in the United States than in this country. In America an inventive idea is regarded as a kind of marketable commodity, while in Great Britain the troubles of the inventor in getting his invention, however meritorious, into commercial form, are proverbial. For this the patent laws of this country are largely accountable. In both the United States and Germany the granting of a patent is a serious process, and one exercised with the greatest possible discrimination. Here anyone may obtain a patent for almost anything, so long as the fees are paid. The consequence is, that while both an American and a German patent are possessed of a certain, though doubtless undetermined, value, owing to the fact that their substance matter has been examined and judged patentable, in England the value of a patent is practically nothing."

It must be admitted that the above estimate of the situation is in the main correct, although there is one important particular to which we must take exception. While the average English patent has no such value as the American or German patent, an exception must be made in the case of the American inventor who, having secured the allowance of his United States patent, proceeds to take out a patent on the same invention in England.

An American patent is only granted after a thorough and painstaking search, not merely of American but all foreign records, has been made and the element of novelty has been clearly established. Hence an American inventor who applies for an English patent stands in the advantageous position of knowing that the novelty of his invention has already been well established, the claims having been drawn to avoid interference with prior English patents. It is obvious, therefore, that when our contemporary says, "in England the value of a patent is practically nothing," it says too much, the English patent of an American patentee having a special value due to the research and care with which the claims have been drawn.

# THE HEAVENS IN MAY, BY GARRETT P. SERVISS.

At 9 o'clock P. M. in the middle of May, the observer of the heavens will notice, directly in the south, a somewhat conspicuous quadrilateral figure among the stars. It is the constellation Corvus. Just above it Virgo appears, with her head upon the meridian and her feet far off toward the east, while her brightest star, Spica, glittering near her girdle, is clearly outshone by the planet Jupiter, which seems to be following from the east. Almost in the zenith a sprinkle of small stars indicates the presence there of Berenice's Hair, while between the zenith and the Pole Star the Great Dipper is balanced across the meridian, the handle to the east and the bowl to the west. Following the arch of the Zodiac westward appear Leo, Cancer, and Gemini, the latter near its setting point. East of Berenice's Hair and north of Jupiter is the great star Arcturus, with the circlet of the Northern Crown not

far away toward the northeast. Below the Northern Crown, the eye, glancing toward the left hand, catches the brilliant rays of Vega in the constellation Lyra. The quadrilateral figure between the Northern Crown and Vega is the central part of the constellation Hercules, and the famous "Great Cluster" of Hercules is between the two stars of the quadrilateral next to the Crown, and nearest to the northern one. A small telescope will show it, on a moonless night, like a round twinkling nebula. Low in the southeast the reddish star Aldebaran has just risen.

#### THE PLANETS.

Mercury is a morning star, best seen about the 9th or 10th, an hour before sunrise. It is not, however, well placed for observation, and, being near aphelion, its brilliancy is diminished. It is in the constellation Pisces

Venus is also a morning star, in Pisces, further west than Mercury, and, of course, more conspicuous. It is slowly overtaking the sun in its eastward motion.

Mars is in the constellation Cancer, between the stars Gamma and Delta, and does not set until late in the evening. The last opposition of Mars seems to have yielded little information to the astronomers. The distance between it and the earth is still rapidly increasing.

Jupiter, in Virgo, rises before sunset and crosses the meridian before midnight at the beginning of the month. Some remarkable changes in the appearance and arrangement of its belts have occurred, and the possessor of a four to six inch telescope will be repaid for any study he may devote to it. On the 5th, at 9:55 P. M., Eastern time, the shadow of Satellite I will appear on the planet. On the 6th, at 9 h. 21 m. 35 s., Satellite I will reappear from eclipse, close to the planet on the east side, a phenomenon worth witnessing, and readily visible with a small telescope. On the 13th the shadow of Satellite II will be seen on the planet after about 7:45 P. M., while Satellite I will be occulted at 8:40. On the 20th, after 10:30 o'clock, the shadows of both Satellites 11 and III will be seen on the planet, the former in advance and passing off a few minutes after 11 o'clock. On the 29th Satellite I will reappear from eclipse at 9 h. 32 m. 21 s., and Satellite II at 9 h. 52 m. 05 s.

Saturn, in Ophiuchus, just north of Scorpio, rises about 8 o'clock P. M. in the middle of the month. It will come into better position for observation in June.

Uranus is an hour ahead of Saturn in rising, but is also in the constellation Ophiuchus, north of the star Antares. It is in opposition to the sun on the 27th.

Neptune is in Taurus about a degree northerly from the star Zeta.

### THE MOON.

New moon occurs on the 9th about noon, first quarter on the 17th about noon, full moon on the 24th about midnight, and last quarter on the 2d about noon.

The lunar conjunctions with the planets take place on the following dates: Venus, 7th; Mercury, 7th; Neptune, 12th; Mars, 16th; Jupiter, 22d; Uranus, 25th; Saturn, 26th.

The moon is in perigee on the 1st, and in apogee on the 16th.

## NATIONAL ACADEMY OF SCIENCES.

BY MARCUS BENJAMIN, PH.D.

The regular annual session of the National Academy of Sciences began its meetings in Washington on April 18. The place of meeting was the auditorium of Columbian University. This organization, as is well known, holds an advisory character to the government, and by law is required to meet on the third Tuesday in April of each year at the capital. Its membership, which is limited to 100, includes only the most distinguished representatives in the various branches of science.

The special interest that is attached to the spring meeting is the business that is transacted, and on the present occasion the various matters discussed made the meeting an important one. The presiding officer was Dr. Wolcott Gibbs, of Newport, R. I., who is now one of the three surviving original founders of the academy. It is not possible to discuss the various papers that were presented before the academy, and we must therefore content ourselves with simply mentioning their names. This action is almost necessary for the reason that many of the distinguished speakers content themselves with simply announcing the papers that they have prepared by title, while others whose papers are more lengthy describe them to the academy in a short extempore summary of their contents. It may be said, however, that the papers by Mr. Charles D. Walcott, Superintendent of the United States Geological Survey, and that by Mr. Henry S. Pritchett, Superintendent of the Coast and Geodetic Survey, and also that by Prof. Newcomb, were essentially descriptive of the work accomplished by the offices under their

"On the Diamond and Gold Mines of South Africa,"
"On the Tawner Deep Sea Tow Net," by Alexander Agassiz; "On the Acalephs of the East Coast of the United States," by Alexander Agassiz and A. G. Mayer; "On the Limestones of Fiji," by E. C. Andrews; and

"On the Bololo of Fiji and Samoa," by W. McM. Woodworth, both of which were communicated by Alexander Agassiz; "On the Development by Selection of Supernumerary Mammæ in Sheep," and a discussion "On Kites with Radial Wings," by Alexander Graham Bell; "Ophiura Brevispina," by William K. Brooks and Caswell Grave; "The Shadow of a Planet," by Asaph Hall; "Remarks on the Work of the Nautical Almanac Office During the Years 1877-98 in the Field of Theoretical Astronomy," by Simon Newcomb; "The Resulting Differences Between the Astronomic and Geodetic Latitudes and Longitudes in the Triangulation along the Thirty-ninth Parallel," by Henry S. Pritchett; and "Progress in Surveying and Protection of the United States Forest Reserves," by Charles D. Walcott.

Of the public business transacted by the academy the following may be mentioned: The six members of the council that were elected were as follows: Prof. Simon Newcomb, Dr. Samuel P. Langley, Mr. Arnold Hague, Prof. George J. Brush, Prof. Henry P. Bowditch, and Dr. John S. Billings. The society has received by bequest on several occasions sums of money which have been invested so as to produce an income for the purpose of conferring medals upon men who have achieved special eminence in certain directions, and the Watson medal, founded by the widow of Prof. James C. Watson, which is of this character, was awarded to Mr. David Gill, the official astronomer of Great Britain at the Cape of Good Hope. The special work for which it was conferred was the perfection of the application of the heliometer to astronomical measurements.

An important feature of the spring meeting is the election of new members, and for the first time in several years the full quota of five, which is the limit imposed by the constitution, was elected. The successful candidates were as follows: Charles Emerson Beecher, who is connected with the paleontological department of Yale University, and who was for many years an assistant of the late Prof. Othniel C. Marsh; Prof. George C. Comstock, the astronomer who holds the office of director of Washburn Observatory in Madison, Wis.; Prof. Theodore William Richards, who is assistant professor of chemistry in Harvard University and the successor of the late Prof. Josiah P. Cooke. Prof. Richards' work on atomic weights has gained for him a more than national reputation; Edgar F. Smith, professor of chemistry in the University of Pennsylvania, whose specialty is the electrolytic deposition of metals; and Edmund B. Wilson, the biologist, who is connected with Columbia University, in New York city.

The Washington Academy of Sciences, a body that has recently been organized, tendered the National Academy a reception, at which a lecture was given by Prof. R. W. Wood, on the subject of photography of sound waves and color photography—arts in which this gentleman has done much that is new within the past few months. His remarks on photographing sound waves were of unusual interest, because they were accompanied by stereopticon slides portraying sound waves in motion, and were, it is claimed, the first ever produced in which the original and reflected waves were both represented on the plates. His exhibition of color photography was equally interesting, and his method of producing directly from nature photographs in the natural colors seems to promise success

The usual social entertainment on this occasion was given by Prof. Alexander Graham Bell.

### A PARISIAN EGG FORGER.

An egg forger has been recently exposed in Paris. Eggs are about the last thing that one would expect to be forged, but it should be remembered that there are many collectors of birds' eggs who are willing to pay a high price for rare birds' eggs. A visitor saw this clever forger make a penguin egg which could not be distinguished from the real one that served him for a model. He made the egg of plaster of Paris which he burnt and glazed. The egg was intended for who furnished eggs for a foreign scientific collection. It is not very difficult to impose on even experienced scientists, for among the real eggs of most species there are so many varieties that even the most practiced expert could not readily distinguish all of them. The eggs of the common fly catcher are very cheap and by chemical treatment they acquire a bluish, green, shiny color, and are then sold at high prices as the eggs of the silk tail. From common ducks' eggs are fabricated eggs of a falcon, being given a silver green color for the purpose. The pigeon and wood pigeon eggs are also transformed into rarer products of birds. Nightingales' eggs are difficult to procure and are therefore rare. They are successfully imitated by coloring larks' eggs brown. For a long time the egg forger was an assistant in a natural history museum in the provinces. There have been other cases of forgery of very rare birds' eggs, but these were only made of excessively rare eggs, and their manufacture did not constitute a permanent means of livelihood.
