avenue, cut through from the avenue of the Champs Elysees and flanked, on either side, by the only permanent buildings of the Exposition, forms the approach to the bridye from the right bank of the Seine. Leaving the bridge on the left side of the river, the visitor at once beholds the snowy whiteness of those exquisite palaces, on either side of the Esplanade des Invalides. that are devoted to exhibits of the Decoration and Furuishing of Public Buildings and Dwellings. These structures are exquisitely frescoed.
From the center of the bridge, looking right and left, or from etther end it, vistas of rare architectural beauty can be obtained.
The bridge has been constructed so as to preserve an uninterrupted perspective, the table of the bridge having been depressed as much as was possible without detriment to navigation on the Seine. Metal has been employed in its construction, riving a great depression, with a platforin thickness reduced toward the middle of the arch. The substructure is composed of fifteen arches of cast steel.
A detailed and fully illustrated description of the construction and engineering features of their handsome structure was given in the Scientific American of March 10, 1900.

To prevent any effect of contraction or dilation of this enormous mass of metal, in any variations of temperature, the arches are joined to the key in a manner that has been seen in the Galerie des Machines and the older bridge Mirabeau.
The massive masonry forming the heads of this noble bridge, adorned with magnificent towers, visible from many distant points of view, constitutes an enduring monument to Messieurs Resal and Alby, engineers in charge of the work.
The laying of the foundation stone of the Pont Alexandre III., formed the most imposingevent of the late memorable visit of the Czar and Czarina, to Paris, particulars of which are still fresh in the public mind.

The total cost of this great work has been $7,000,000$ The total cost of this great work has been $7,000,000$
francs, $1,000,000$ having been spent on the decorations alone

## A PAIR OF CURIOUS RELICS AT ABERFOYLE, SCOTLAND.

In the earlier half of the century the practice of stealinir bodies from the churchyards where they had been interred, tor the purpose of sale as subjects for dissection, which was known as "body-snatching," was for a time very rife.
Various plans were made to defeat the nefarious and sacriligious proceedings of the "body-snatchers" or "resurrectionists" as they were sometimes called, a very common one being the erection of two or more small watch-houses whose windows commanded the whole burying ground and in which the friends of the Heceased mounted guard for a number of nights after the funeral.
A usual method of the grave-robbers was to dig down to the head of the coffin, bore in it a large round hole by weans of a specially constructed center bit and haul the body to the surface with a hook-rope. It was to counteract this maneuver that the two curious coffin-like relics now lying on either side of the door of the ruined church of Ab erfoyle in Perthshire, were constructed. They are solid masses of cast iron, and, as may well be imagined, of enormous weight. On the upper side of each are provided two loops or handles.
When an interment took place one of these massive slabs was lowered by suitable derricks, tackles and chains onto the top of the coffin, the grave was filled in and there it was left for some considerable time. Later on the grave was opened and the iron armor plate was removed and laid aside ready for another funeral.
Although these contrivances have not been used for many years, they still lie on the grass of the lonely little church yard, objects of curiosity to the passing cyclist and tourist.

A submarine cable in actual use will form one of the A SUBMARINE cable in actual use will form one of the
exhibits of the Paris Exposition. It will run from thd Electricity Building to the Vincenues Annex several miles distant along the Seine. A complete cable station will be operated at each end to show the public how trans-oceauic messages are transmitted and received. Souvenir messages way be sent by the public.
second plate, exactly under the same conditions regard. ing speed, light, etc., as the first, yet the plate ultimately turus out a dismal failure. The exposure proves to be many seconds too short, and the picture is scarcely visimany seconds too short, and the picture is scarcely visi
ble upon the negative. But ascend another 200 or 300 feet, expose again, and you get a result equal in every respect to that obtained at an altitude of 300 feet. There seems to be a thin filwy cloud (not of vapor), that floats above the earth, which appears to have a. non actiniceffect upon the plate, and therefore it is under exposed. This phenomenon is apparent to the naked eye
The accompanying illustration shows the crowd who have watched a balloon ascent It was snapped at a height of 300 feet, and everything is as sharp and distinct as could be desired. It was not taken under the most advantageous conditions, since the sun was low down in the heavens-see the long shadows cast upon the ground-and there fore the light was inclined to be a little yel lowish in color. As a rule an aerial photo i rather flat and uninteresting, owing to the lack of half-tones and shadows, but this photograph is full of life and vigor.

## Phosphate Deposits in Christmas. Island.

Christmas Island is situated 190 miles south of Java, being 12 miles long by 4 to 9 miles wide, having an area of 43 square miles. Its climate is favorable, the tewpera ture varying from $20^{\circ}$ to $30^{\circ}$ C.; the soil is very fertile, and contains from 8 to 30 pe cent of phosphate of lime. The trees have a remarkable development; in some place the sago palim reaches a height of 60 to 70 feet Among the representants of the fauna and flora of the island are a few species which exist nowhere else; for instance, a bat o unusual size, which flies in bright sunlight an owl whose cry resembles the barking of

armor-plate for coffins-a relic at aberfoyle, scotland.
ot present themselves to the photographer who plies his work on terra firma. In the first place, it is im perative that the camera should be provided with a rapid lens, which also possesses long range, and yet givesclear and sharp definition. Again, the magazine contrivance must be of the simplest, quickest, and most reliable description, since one has but very little time to change the plates. When a balloon leaves the earth its upward flight at first is often at the pace of 500 feet per minute, gradually decreasing until it at tains its equilibrium. It will be seen from this fact that the operator has to be a very quick worker. The plates must be of exceptional rapidity, since the exposure must be remarkably short; otherwise the re sultant photo will be blurred. Cases have been known in which a shutter working instantaneously at the one hundredth part of a second has been too slow, though it would have been quite rapid enough to snap an ex press train traveling at 60 wiles an hour: but in such press train trave quil cases the velocity of the rivig balloon has been excep ional. The photographer has no need to trouble about his view-finders. He simply points the camera downward, in the desired direction, and snaps his shut ter as rapidly as he can work.

Butaerial photography is full of disappointing failures. The aeronaut who secured the accompanying photograph has, on several occasions, ascended in a balloon with his camera fully loaded with forty films and has exposed the whole of them at varying altitudes; yet when they were developed they were found to be absolutely useless. The atmosphere plays an important part in the success of an aerial photograph At an altitude of $\mathbf{3 0 0}$ feet a magnificent result may be obtained. You ascend another 100 feet, and expose
a small dog, and a terrestrial crab which climbs trees, etc. The first mention of this island dates back to 1666 , when it figures upon the maps of the time under the name or Moni ; on latermaps it is called Moni or Christmas Island. The great difficulty encountered in landing and in mounting the heights prevented, for a long time, the thorough exploration of the island. In 1888 the "Challenger" expedition made a landing and devoted ten days to a thorough exploration ; paths were traced to the summit, and a great many specimens of minerals as well as of the fauna and flora were sent to England. Among the minerals, the samples of rich phosphates attracted attention and led to a more thorough investigation; a fresh supply of specimens was obtained, and it was found on analysis that the percentage of phosphates reached as high as 80 to 92 per cent.

Mr. Andrews, who was sent to the island to study the phosphate deposits, considers them to be formed by the accumulation of excrements of myriads of sea birds which inhabited the island, which was formerly low and free from forests. Several years aro Mr. Murray of the "Challenger" expedition, and Mr. George Ross established themselves on the island and secured more than 200 specimens, which they had analyzed. The Christmas Island Phosphate Company was formed, which worked a part of the deposits, especially that of the phosphate hill, where a railroad was built to the point of disembarking $11 / 2$ miles distant, and special loading apparatus was erected. Several shipments have been made to London, the amount reaching 6,000 tons, and the results having proved satisfactory, they will be continued. The British Museum has recently published a series of observations relating to the geological formations and the fauna and flora of the island, which have been obtained by Mr. Andrews and others.

For several years Prof. Omori has studied the subject of earthquake measurement in a brick building, says Nature. One of Prof. Ewing's horizontal pendulum seismographs was fixed near the top of an external wall of the Engineering College at Tokyo, while another was erected on the ground below. During the years 1894-98, ten moderate earthquakes were recorded, and it was found that if the earthquakes consisted of comparatively slow vibrations (say, above half a second in duration), the motion was practically the same in both places: but if of quick-period vibrations, the motion of the top of the wall was about twice as great as that of the ground. Prof. Omori notices that, with destructive earthquakes, the damage of two-storied buildings is generally confined to the upper story
