gation, and lifting fourteen hundred gallons per minute —equal to one hundred and fifty-five miner's inches. Up to the present time the motor has produced results equal to about ten horse power, but fifteen is claimed for it.

The motor is the result of a number of experiments by a band of Boston capitalists. One of the first productions was a silver reflector, which cost many thousands of dollars, but was abandoned. The next was modeled after the Ericsson machine of 1884; but it was a failure. A third was erected at Longwood, proving also a failure. A fourth attempt was made, this time in Denver, which was fairly successful, doing onehalf the work of the Pasadena model. Finally the latter was produced and found to be a success. A duplicate, perhaps improved, will be erected at the Pan-American Exhibition. Dwellers in the East, where rain falls every few days throughout the year, cannot realize what such a perfected motor means to the West, where arid lands await but the flow of water to blossom as the rose. In such regions-and they represent millions of square miles-fuel is usually very scarce, often being so important a factor that the question of it determines the success or failure of the work. This is essentially true of the Californian desert and vast regions in Colorado, Utah, and surrounding States and Territories. Mines and pumping plants are often far from railroads, and in sections where no fuel is in sight, wood and coal being hauled from long distances. In such locations the solar motor is a boon. The skies are comparatively free of clouds, and the machine can begin work an hour after sunrise, possibly earlier, and continue until half an hour before sunset. It is possible that with cheaper methods of storing electricity sufficient power may be stored during the day to run the engine at night, or during the absence of the sun. Inventors are already experimenting upon methods of increasing the effectiveness of the motors, and probably larger ones, and groups of them, will be seen in the near future.

No invention of modern times has given such an impetus to the development of arid lands as the solar motor, and it has been visited by many interested in the question. The development of Lower California has been seriously impeded by the lack of fuel; the country being dry and barren in localities where rich mines are known to exist. The country is cloudless for months—in every sense the land for the solar motor, as water underlies the surface almost everywhere, and when pumped up and sent out upon the soil the region, which was formerly a desert, can be made fertile and literally to blossom as the rose.

THE FLEMING SAFETY COLLAR FOR SHAFTS.

Many of the accidents which occur in machine-shops and factories are due to the old-fashioned projecting set-screw by which collars are usually held on shafts. These set-screws have been condemned by factory inspectors, and even prohibited by law, for which reason they have often been countersunk, thus weakening the collar. Moreover, the collar is held in place only by bearing of the set-screw on the shaft. If the bearingpoint slip, the collar moves from its place, thereby deranging the shafting and causing belts to slide from their pulleys.

These difficulties have been very simply and effectively overcome in the Fleming safety-collar, to which our attention has been called by Mr. W. H. Davis, P. O.

Scientific American.

of the machinery; the collar is held to the shaft, not at one point alone, but through its entire length and internal circumference.

The fact that the collar can be applied to a shaft

PARTIAL SECTION OF THE COLLAR.

without removing any machinery is in itself a significant feature. In all collars now used, the machinery on the end of the shaft must be taken off before the collar can be slipped on. The time, labor, and expense thus involved are items which are by no means small. Moreover, the cost of manufacture is no more than that of any collar now in use.

AN EFFICIENT SINGLE-PULL CEILING-SWITCH.

From the electrician's standpoint it cannot be denied that the ceiling-switch has merits which commend it to every consumer of electricity. It can be placed exactly where it is needed, and it dispenses with the wires which ordinarily run down to a suitable point on a wall. But these obvious merits have been more than offset by the mechanical defects which are unfortunately too often found in ceiling-switches. The two unsightly cords which form a part of most switches of this type cannot be manipulated with that ease which should be one of the distinguishing features of every electrical appliance. Our attention has been drawn to a novel switch made by J. Jones and Son, of

THE JONES SINGLE-PULL CEILING-SWITCH.

64 Cortlandt Street, Manhattan, New York city, which so far improves upon most ceiling-switches that the difficulties usually presented have been overcome.

The improved switch is a single-pull switch. By drawing downward on a single chain or cord, the circuit is opened or closed. Mechanically considered, the switch consists of a bed-plate screwed to the ceiling, which bed-plate carries the fixed contact-points and the switch-arms or blades, one of which is loosely pivoted and the other mounted on a rock-shaft. The rock-shaft carries a rock-arm and a crank, both of which have partial rotation in opposite directions. The crank is connected by a coiled spring with a crosspiece extending between the two switch-arms. The rock-arm is pivotally connected by means of a link with a crank-pin on a disk actuated by a spring-drum, to which a pull-chain is attached. A pull upon the chain first winds the spring of the drum, then turns the disks and with it the crankpin, through one-half a revolution As the crank-pin turns, the link is thrown forward, thereby swinging the rock-arm and the crank on the rock-shaft in opposite directions. As a result of this movement, the end of the rock-arm is made to engage an elbow-lever which assists in swinging the switch-arm out, and the crank

MARCH 16, 1901.

is made to extend the spring by which it is connected with the cross-piece uniting the switch-arms. The switch-arms partially swung by the elbow-lever and by the strain on the coiled spring, are automatically carried entirely away from the contacts by the action of the extended coil-spring. This movement of breaking the circuit is effected with the utmost rapidity. When the pull-chain is released the drum is carried back by its spring without in any way disturbing the disk or the remaining parts.

In order to close the circuit it is necessary merely to pull the chain again. The disk is then made to rotate through the remaining half of its revolution, thereby throwing the rock-arm and crank back to their initial positions, rocking the shaft, and extending the coiled spring. When the crank to which the coiled spring is secured passes the vertical the switch is automatically closed by the action of the extended spring. In both making and breaking the circuit the switch-arms are first partially swung and are then automatically actuated by the coiled spring.

A careful examination of the device convinces us that it is both quick and efficient in its operation.

A FOLDING BUNK FOR CARS AND SHIPS.

In emigrant or transport ships and cars it is often necessary to erect a large number of separate bunks, so arranged that they may be easily removed. A bunk of this type has been devised by John P. Lein, a New York inventor.

On two uprights or supports holders are carried having a slot with an upwardly-extended portion. Above the holders each of the supports carries hooks. The

A FOLDABLE AND REMOVABLE BUNK.

bunk itself is provided with contracted necks, which are received by the upwardly-extending slots. Chains attached to the outer side of the bunk are hung on the hooks to support the bunk.

In order to fit out a ship it is necessary merely to erect the uprights, insert the bunk-necks in the slots of the holders, and hook the chains in place. When not in use the bunk can be folded simply by turning it in the holders so that the link of each chain nearest the outer edge will engage the hook. The entire bunk can be readily removed whenever desired.

The Current Supplement.

The current SUPPLEMENT, No. 1315, has many interesting articles. "The Evolution of the Adobe" is by C. F. Holder, and is accompanied by several illustrations. "Cameos" is by Cyril Davenport, F.S.A. "Optics of Trichromatic Photography" is continued. "Dock Equipment for the Rapid Handling of Coal and Ore on the Great American Lakes." by Arthur C. Johnston, is accompanied by many illustrations. Several articles in this issue are devoted to the consideration of modern commerce. "Women Astronomers" is by J. E. Gore. "Progress of Agriculture in the United States" is by George K. Holmes, and is a valuable article. "Britain's Leaning Towers" describes two curious examples. The recent Berliner patent decision is carefully digested. "Excavations at Carthage" describes some important discoveries. "Constellation Figures as Creek Coins" is by Robert Brown, Jr., and is a curious study in numismatics.

THE PARTS OF THE FLEMING COLLAR DETACHED.

Box 305, Montreal, Canada, and in which the set-screw is entirely abandoned. The Fleming collar comprises essentially four pieces — two symmetrical, tapering, threaded and flanged semi-cylinders, which embrace the shaft, a threaded locking-ring which binds the semicylinders firmly to the shaft, and a toothed grippingkey, A, received by an opening in one of the semicylinders and forced into engagement with the shaft by the locking-ring.

The merits of this arrangement are obvious. The setscrew is entirely dispensed with; the members can be taken from the shaft without removing any other part
