

incline of 28 centimeters per meter. It would be difficult to imagine a spectacle more curious, more interesting. The experiments were made in the presence of M. Dumon, Minister of Public Works. As he entered the Gardens, the carriage, filled with two bags containing each 30 kilogrammes of sand, shot down with frightful rapidity, and, after having encircled the spiral, came to a stop beneath the windows of the first story of the house occupied by Madame Aguado,

PACIFIC WIRELESS TELEGRAPH OFFICE.

with such precision that a bouquet of flowers would have fallen more heavily at the feet of the noble lady. M. Thiers was present at the trial. He complimented M. Clavières, the engineer, in the most flattering terms on the accuracy of his calculations, on the precision with which he had solved the problem of centrifugal force. The next day, living passengers took the place of the bags and returned sound and well after their exciting experience." History does not record the emotions of Madame Aguado, "the noble lady."

"Looping the Loop" soon went out of fashion. The public in that day was just as fickle as it is now. About 1865, however, an ambitious Barnum thought it would be a most excellent scheme to equip the Circus Napoleon with a centrifugal railway. The car, however, was derailed on the very first trip, and the Prefect of Police, who was at that time M. Boitelle, forbade further harrowing journeys. After a lapse of nearly half a century, the centrifugal railway again made its appearance, this time in America, at Coney Island. The particular form here adopted developed into the more dangerous "Looping the Loop" for bicycles. The principle still remains substantially the same as in the old days. Still another modern instance justifies Solomon's old saw.

#### SANTA CATALINA'S WIRELESS NEWSPAPER. BY CHARLES F. HOLDER.

The island of Santa Catalina is a part of Los Angeles County, Southern California, lying about twenty

THE PACIFIC WIRELESS TELEGRAPH STATION.

miles off shore, parallel with the mainland. The principal settlement or town is at Avalon, on the south-east, where one of the quaintest hamlets of the coast has grown up, having a summer population of six thousand or more and a rapidly-growing one in winter. The locality has much to recommend it—an almost perfect climate the year around, and sports and pastimes which have given it a world-wide reputation.

There has been one drawback to Santa Catalina, and that was the lack of telegraphic communication. In summer there are from two to three boats daily; but in winter only one, the steamer arriving at noon. For twenty-four hours the island was virtually without communication with the mainland. To remedy this, the Banning Company, who own the island, established a pigeon route. Large flocks of these birds were trained, and telegrams or important news were sent in this manner with success, the birds taking a message from Avalon to Los Angeles, a distance of fifty-five miles, in about an hour. The pigeon houses were so arranged that when a bird arrived with a message it rang an electric alarm in the receiver's home or office, thus calling him up.

But there was an element of uncertainty in this. Sportsmen who did not know that the birds were tame shot them *en route*. Others died of over-exertion. In the main the service was satisfactory, but so many prominent men visited the island that the need of adequate means of communication became more and more urgent. Finally Gen. A. L. New, vice-president of the Pacific Wireless Telegraph Company, suggested the installment of a wireless telegraphic plant. A point was selected north of Avalon Bay on the conspicuous headland that culminates in Sugar Loaf rock and is reached by a well-built stage road. Here the mast was erected and the office built, the latter being connected with a main office on Ocean Avenue, Avalon. The instruments used, notably the receiver, were designed by Mr. Swenson.

The nearest mainland point is at San Pedro, about thirty miles distant, and from the time the office opened for business to date, about six thousand messages have been sent without a single error or a moment's delay. The plant has been subjected to some severe tests. During the last of March a terrific storm of wind and rain very nearly cut off boat communication with the island; yet the messages were sent across the channel with directness and precision.

It is interesting to note that while the London Times is experimenting with "marconigraphs," endeavoring to test the accuracy of the system, the Pacific Wireless Telegraph Company has been for several weeks in business, supplying Santa Catalina through a daily paper, the Wireless, with all its news. The Wireless is a small newspaper containing the condensed news of the day—a perfect busy man's paper. The Avalon Wireless publishes every morning the news of Santa Catalina, the latest catches of great game fishes on the Isle of Summer, as well as the telegraphic news of the world, sent across the channel during the night.

#### DUST STORM OBSERVATIONS.

Prolonged and elaborate researches have been carried out by two eminent scientists, Profs. Hellman and Meinardus, relative to the dust-storm which swept over the coasts of Northern Africa, Sicily, Italy, Austria-Hungary, Prussia, part of Russia, Denmark, and the British Isles between March 12 and 19 of 1901, and the results are of valuable interest and importance to meteorological science. Dust storms on a large scale are rare occurrences even in Africa. The track of this storm was traced by Profs. Hellmann and Meinardus with accuracy, and its origin located. The dust originated in storms occurring on March 8, 9 and 10 in the desert of El Erg, situated in the southern part of Algeria, which carried the dust and transported it northward. It began to fall at Algiers and Tunis in a dry state on the night of the 9th. The subsequent falls gradually took place northward, first Sicily, then Italy, the Alps, Austria-Hungary, Germany, Denmark and European Russia, in the order named, receiving their share. In Sicily and Italy the dust fell without the aid of rain, but elsewhere it was only noticed during or after showers. The quantity of dust deposited on the earth gradually became less as it traveled northward, while the fineness increased as the quantity diminished. The dust was not distributed homogeneously over the land surface, but in patches and streaks, some places being entirely free from it, while in others the fall was specially dense. The unequal distribution and different values for the rate of movement of the dust cloud are explained by the variable velocity of air currents and the changing position of the barometric depression. The investigation has conclusively proved that the dust was carried by a large mass of air which moved with great velocity

from Northern Africa to the north of Europe, and that this mass of air, cyclonic in character, was led on its western side by air currents from the north, and on its eastern side by southerly currents. The total amount of dust that fell to the surface on that occasion is roughly estimated to be about 1,800,000 tons, of which at least two-thirds were deposited to the south of the Alps.

All the microscopic and chemical analyses point to this dust being neither volcanic nor cosmic, but solely such as is found in the Sahara desert and other parts of Africa. It was different with the dust showers which succeeded the eruptions of Krakatoa in May and August of 1882, which were collected at various distances, the greatest being more than 1,100 miles from the seat of the disturbance. In our latter instance the dust collected was invariably of volcanic origin, and the tremendous height to which the particles were thrown, coupled with the movement of the air at that altitude, was responsible for the dust remaining suspended in the atmosphere for so long, and also for the brilliantly-colored sunsets observed nearly all over the world. Dust-falls afford a means of obtaining further knowledge of the actual movements of the air currents in the higher reaches of our atmosphere which cannot be gained by any other methods, and are therefore of great meteorological value, but it is seldom that the fall occurs over an area where such useful data can be secured as was the case with the dust-storm of March, 1901.

#### The Current Supplement.

The current SUPPLEMENT, No. 1427, is in every way

INTERIOR OF THE SANTA CATALINA WIRELESS TELEGRAPH PLANT.

a noteworthy number. Mr. Day Allen Willey has prepared a full account of the famous Krupp works at Essen, which account is to appear in two installments. The first installment is published in this issue. Admirable illustrations add much to the interest of the text. Radio-active substances, the nature of which is still but ill-understood, are discussed in a valuable article by the famous chemist Becquerel. Mr. Guarini concludes his exhaustive review of the development of Marconi's system of wireless telegraphy. Sisal fiber has already been discussed in the SUPPLEMENT. Additional information on the fiber is now published, together with reproductions of some striking photographs. Lieut.-Col. H. A. Yorke, an English army officer, recently visited the United States for the purpose of studying American railways for the London Board of Trade. His report is published in the SUPPLEMENT. The launch of the Argentine cruiser "Moreno" is described and illustrated. W. J. Tennant explains in a simple way, without mathematics, the principle of the planimeter. A. Gehlen presents a scholarly summary of the latest researches on the discovery of America by the Northmen.

The North-Eastern Railroad of Great Britain, which decided a short time ago to adopt motor cars upon a certain section of its system, has had three types of motors already delivered to it for experimental purposes. The cars are fitted respectively with a 33 horse power Napier, a 95 horse power Wolseley, and a 100 horse power Automotor engine. There is a special interest to automobilists attached to the trials with these respective motors, since they will afford some conclusive data regarding the advantages and disadvantages of horizontal and vertical engines, as they will run under precisely similar conditions. The Napier and Automotor engines represent the vertical engine, and the Wolseley the horizontal motor type.
